On Strongly Controllable Group Codes and Mixing Group Shifts: Solvable Groups, Translation Nets, and Algorithms

Kenneth M. Mackenthun Jr.

October 5, 2008

Abstract

The branch group of a strongly controllable group code is a shift group. We show that a shift group can be characterized in a very simple way. In addition it is shown that if a strongly controllable group code is labeled with Latin squares, a strongly controllable Latin group code, then the shift group is solvable. Moreover the mathematical structure of a Latin square (as a translation net) and the shift group of a strongly controllable Latin group code are closely related. Thus a strongly controllable Latin group code can be viewed as a natural extension of a Latin square to a sequence space. Lastly we construct shift groups. We show that it is sufficient to construct a simpler group, the state group of a shift group. We give an algorithm to find the state group, and from this it is easy to construct a strongly controllable Latin group code.

1 Introduction

Kitchens introduced the fundamental idea of a group shift and showed that a group shift is a shift of finite type [1]. A group shift is essentially a time invariant group code. Forney and Trott showed that a group code has a well defined state space and can be represented on a trellis, and a strongly controllable group code can be realized with a shift register [2]. In a following article, among other results, Loeliger and Mittelholzer gave an abstract characterization of the group which can appear as the branch group of a strongly controllable group code, which they call a *group with a shift structure* [3].

In this paper, we give a simple characterization of a group with a shift structure, or *shift group*. We show that a shift group G involves a normal chain $\{X_j\}$ and a tower of isomorphisms using groups in the normal chain. In addition, there are two important normal subgroups X_0 and Y_0 of G which have normal chains which also characterize the shift group. These results are shown in Section 2.

In Section 3, we use the theory of translation nets to show that if a group code is strongly controllable and is labeled with Latin squares, the shift group is solvable. We show that Latin squares which can appear in a Latin group code are isotopic to those constructed by the automorphism method of Mann [19]. It is shown that if a group code is strongly controllable and if $X_0 \cap Y_0 = \mathbf{1}$, $X_0 \simeq Y_0$, and X_0 is elementary abelian, then a complete set of mutually orthogonal Latin squares can be used to label the group code (throughout the paper, we use $\mathbf{1}$ for the identity of a group). We show that the structure of a shift group is closely related to the structure of a Latin square as a translation net.

In Section 4, we show that a shift group with $X_0 \cap Y_0 = \mathbf{1}$ can be represented as a subdirect product group. Then we give necessary and sufficient conditions for a subdirect product group to be a shift group. These conditions show that to find a shift group it is sufficient to construct the state group of a shift group. We give a characterization of the state group.

Lastly in Section 5, we give an algorithm to find the state group of a shift group; this can be used to find a Latin group code.

2 Shift groups

Let $\mathcal{G}$ be any graph with vertices $\mathcal{V}$ (also called states) and edges $\mathcal{E}$; in shorthand we write $\mathcal{G} = (\mathcal{V}, \mathcal{E})$. We say a graph $\mathcal{G}$ is *l-controllable* if for any ordered pair of states (s, s') in $\mathcal{G}$, there is a path of length l from s to s' in $\mathcal{G}$. A graph that is l-controllable for some integer l is said to be *strongly controllable*. The least integer l for which a strongly controllable graph $\mathcal{G}$ is l-controllable is denoted as ℓ, and we say $\mathcal{G}$ is ℓ-controllable. In this paper, we only study the case $l = \ell$.

The preceding definition uses the idea of controllability in systems theory and the theory of convolutional codes. There is a similar notion in the theory of symbolic dynamics, drawn from ergodic theory. A graph $\mathcal{G}$ is *primitive* if there is a positive integer M such that for any ordered pair of states (s, s') in $\mathcal{G}$ and any $m \geq M$, there is a path of length m from s to s' in $\mathcal{G}$ [11]. If a graph has an edge into each state, then an ℓ-controllable graph is primitive with $M = \ell$.

In this paper, we consider a particular graph constructed using a group B, where the edges $\mathcal{E}$ form group B, and the vertices $\mathcal{V}$ form a quotient group in B. We denote this graph as $\mathcal{G}_B$. We now discuss this construction in more detail.

Let B be a finite group which contains normal subgroups B^+ and B^- such that B/B^- is isomorphic to B/B^+ via an isomorphism $\psi : B/B^- \to B/B^+$. Let π^+ be the (natural) map which sends each element of B to the coset of B^+ that it belongs to; likewise for $\pi^- : B \to B/B^-$. Let $\mathcal{G}_B = (\mathcal{V}, \mathcal{E})$ be the graph with vertices $\mathcal{V} = B/B^+$ and edges $\mathcal{E} = B$, such that each edge $e \in \mathcal{E}$ has initial state $\mathtt{i}(e) = \pi^+(e)$ and terminal state $\mathtt{t}(e) = \psi \circ \pi^-(e)$. (This discussion is taken from Problem 2.2.16 of [17], which is based on [2, 3].) It is known that the edge shift of graph $\mathcal{G}_B$ is a group shift, and moreover, any group shift which is also an edge shift can be modeled in this way [17, 2].

We want to determine when graph $\mathcal{G}_B$ is ℓ-controllable. As in [3], consider all paths $e_0, e_1, \ldots e_j, \ldots$ in $\mathcal{G}_B$ which begin in the identity state, i.e., $\mathtt{i}(e_0) = B^+$. Let B_j^+, $j \geq 0$, be the set of all edges e_j on such paths. Similarly, consider all paths $\ldots e_{-j}, \ldots e_{-1}, e_0$ in $\mathcal{G}_B$ which end in the identity state, i.e., $\mathtt{t}(e_0) = B^-$. Let B_j^-, $j \geq 0$, be the set of all edges e_{-j} on such paths. Note that $B_0^+ = B^+$ and $B_0^- = B^-$. Also note that $B_j^+ \lhd B$ and $B_j^- \lhd B$ [3]. The next result follows directly from work in [3].

Proposition 1 *The graph $\mathcal{G}_B$ is ℓ-controllable if and only if $B_\ell^+ = B$, or equivalently, if and only if $B_\ell^- = B$.*

We denote the normal series $B_{-1}^+, B_0^+, B_1^+, \ldots B_\ell^+$ by the notation $\{B_j^+\}$, where B_{-1}^+ is the identity $\mathbf{1}$ of B, and the normal series $B_{-1}^-, B_0^-, B_1^-, \ldots B_\ell^-$ by the notation $\{B_j^-\}$, where B_{-1}^- is the identity $\mathbf{1}$ of B. Loeliger and Mittelholzer give a definition of a group with a shift structure which uses $\{B_j^+\}$, $\{B_j^-\}$, and intersection terms [3]. Here we study a simpler definition which uses just $\{B_j^+\}$ and B_0^- [13, 14]. Consider a group G with a normal series

$$\mathbf{1} = X_{-1} \subset X_0 \subset X_1 \subset \cdots \subset X_\ell = G,$$

where X_{-1} is the identity $\mathbf{1}$ of G. We denote the normal series $X_{-1}, X_0, \ldots X_\ell$ by $\{X_j\}$.

Definition 1 We say a group G has a *shift structure* $(\{X_j\}, Y_0, \varphi)$ if there is a normal chain $\{X_j\}$ with $X_\ell = G$ and each $X_j \lhd G$, a normal subgroup Y_0, and an isomorphism φ from G/Y_0 onto G/X_0 such that

$$\varphi(X_j Y_0/Y_0) = X_{j+1}/X_0 \tag{1}$$

for $-1 \leq j < \ell$.

We say G is a *shift group* if it has a shift structure $(\{X_j\}, Y_0, \varphi)$. •

Remark: Note that $G/Y_0 \simeq G/X_0$ implies $|Y_0| = |X_0|$ [3]. Furthermore, using (1) for $j = \ell - 1$, we have $\varphi(X_{\ell-1}Y_0/Y_0) = X_\ell/X_0$. This means $X_{\ell-1}Y_0 = G$. Lastly, note that (1) holds trivially for $j = -1$.

Theorem 2 *If the graph $\mathcal{G}_B$ is ℓ-controllable, then B has a shift structure $(\{B_j^+\}, B_0^-, \psi)$.*

Proof If the graph $\mathcal{G}_B$ is ℓ-controllable, there is a sequence $\{B_j^+\}$ with $B_\ell^+ = B$. It is easy to see that each $B_j^+ \lhd B$ [3]. We know that the terminal states of B_j^+ are the initial states of B_{j+1}^+. But the terminal states of B_j^+ are $\psi(B_j^+ B_0^-/B_0^-)$, and the initial states of B_{j+1}^+ are B_{j+1}^+/B_0^+. Thus we must have

$$\psi\left(\frac{B_j^+ B_0^-}{B_0^-}\right) = \frac{B_{j+1}^+}{B_0^+}$$

for all j, $-1 \leq j < \ell$. This proves (1) of Definition 1. •

Let G be a group with a shift structure $(\{X_j\}, Y_0, \varphi)$. We define $\mathcal{G}_G$ to be a graph analogous to $\mathcal{G}_B$, that is, $\mathcal{G}_G$ is the graph $(\mathcal{V}, \mathcal{E})$ with vertices $\mathcal{V} = G/X_0$ and edges $\mathcal{E} = G$, such that each edge $e \in \mathcal{E}$ has initial state $\mathtt{i}(e) = \pi_X(e)$ and terminal state $\mathtt{t}(e) = \varphi \circ \pi_Y(e)$, where φ is an isomorphism $\varphi : G/Y_0 \to G/X_0$, and π_X, π_Y are the natural maps $\pi_X : G \to G/X_0$, $\pi_Y : G \to G/Y_0$.

Theorem 3 *Let $(\{X_j\}, Y_0, \varphi)$ be a shift structure for some group G. Then the graph $\mathcal{G}_G$ is ℓ-controllable.*

Proof We show that $\{X_j\}$ gives a sequence of edges which form well defined paths. We must show that the terminal states of X_j are the initial states of X_{j+1}. But the terminal states of X_j are $\varphi(X_j Y_0/Y_0)$, and the initial states of X_{j+1} are X_{j+1}/X_0. Since

$$\varphi(X_j Y_0/Y_0) = X_{j+1}/X_0$$

by assumption, $\{X_j\}$ gives a well defined sequence of edges. But we know that $X_\ell = G$; thus $\mathcal{G}_G$ is ℓ-controllable by Proposition 1. •

The proofs of the above two theorems are patterned after corresponding proofs in [3]. These two theorems give the following important corollary.

Corollary 4 *The graph $\mathcal{G}_B$ is ℓ-controllable if and only if B is a shift group with shift structure $(\{B_j^+\}, B_0^-, \psi)$. An analogous result holds for graph $\mathcal{G}_G$.*

We pause here to give two useful technical lemmas. The following lemma is an easy extension of the first isomorphism theorem.

Lemma 5 *Let H and H' be groups and consider any homomorphism f from H onto H'. If H_1' is any normal subgroup of H', then $f^{-1}(H_1')$ is a normal subgroup of H and $H/f^{-1}(H_1') \simeq H'/H_1'$.*

Lemma 6 *Let groups Q', Q, R', and R satisfy $Q \subset R$, $Q' \subset Q$, $R' \subset R$, $Q' \subset R'$, $R' \cap Q = Q'$, and $R = QR'$. Assume that $Q \lhd R$, $R' \lhd R$. There are three results:*

$$\frac{Q}{Q'} \simeq \frac{R}{R'} \tag{2}$$

with assignment $qQ' \mapsto qR'$ *for* $q \in Q$,

$$\frac{R}{Q} \simeq \frac{R'}{Q'}, \tag{3}$$

and

$$\frac{R}{Q'} \simeq \frac{Q}{Q'} \times \frac{R'}{Q'}. \tag{4}$$

Proof It is clear $R'R = R'Q$. Then

$$\frac{R'R}{R'} = \frac{R'Q}{R'}. \tag{5}$$

By the second isomorphism theorem, there is an isomorphism

$$\nu : \frac{R}{R' \cap R} \to \frac{R'R}{R'},$$

and an isomorphism

$$\nu' : \frac{Q}{R' \cap Q} \to \frac{R'Q}{R'}.$$

Then using (5) there is an isomorphism

$$\nu^{-1} \circ \nu' : \frac{Q}{R' \cap Q} \to \frac{R}{R' \cap R},$$

or just

$$\nu^{-1} \circ \nu' : \frac{Q}{Q'} \to \frac{R}{R'}.$$

Thus there is an isomorphism

$$\frac{Q}{Q'} \simeq \frac{R}{R'},$$

with assignment $qQ' \mapsto qR'$ for $q \in Q$. This proves (2).

We now show (3). Since $R = QR'$, each coset of Q in R must contain a representative in R'. But the representatives of R' in Q are Q'. Thus each coset of Q in R contains one and only one coset of Q'. Then it is clear that we can define a 1-1 correspondence between cosets of Q' in R' and cosets of Q in R, and this gives the isomorphism in (3).

We know that $Q' \lhd R$. From the preceding paragraph, each coset of Q in R contains one and only one coset of Q' in R'. Then

$$\frac{R}{Q'} = \left(\frac{Q}{Q'}\right)\left(\frac{R'}{Q'}\right).$$

Since each coset of Q in R contains one and only one coset of Q', this means $(Q/Q') \cap (R'/Q') = \mathbf{1}$. Also we have $Q/Q' \lhd R/Q'$ and $R'/Q' \lhd R/Q'$. Then (4) follows. •

We now discuss Figure 1, which shows the relationship of some important groups in G. Note that groups in the same column are subgroups of the group at the top.

$$\begin{tikzcd}
G \arrow[r, "\pi_Y"] & G/Y_0 \arrow[r, "\varphi"] & G/X_0 & G \arrow[l, "\pi_X"'] \\
X_{j+1} \arrow[r] & X_{j+1}Y_0/Y_0 \arrow[r] & X_{j+2}/X_0 & X_{j+2} \arrow[l] \\
X_j^* \arrow[dr] & & & \\
X_j \arrow[r] & X_jY_0/Y_0 \arrow[r] & X_{j+1}/X_0 & X_{j+1} \arrow[l] \\
\mathbf{1} \arrow[r] & Y_0/Y_0 \arrow[r] & X_0/X_0 & \mathbf{1} \arrow[l]
\end{tikzcd}$$

Figure 1: Relationship of groups in G.

Examine the left side of Figure 1. Fix j, $-1 \le j < \ell$. The natural map $\pi_Y : G \to G/Y_0$ is defined by the assignment $g \mapsto gY_0$. Let $\pi_Y|X_{j+1}$ be the restriction of π_Y to X_{j+1}. Then $\pi_Y|X_{j+1}$ is an onto homomorphism $\pi_Y|X_{j+1} : X_{j+1} \to X_{j+1}Y_0/Y_0$. Now X_jY_0/Y_0 is a normal subgroup of $X_{j+1}Y_0/Y_0$. Then from Lemma 5, $(\pi_Y|X_{j+1})^{-1}(X_jY_0/Y_0)$ is a normal subgroup of X_{j+1} (we call it X_j^*), and

$$\frac{X_{j+1}}{X_j^*} \simeq \frac{X_{j+1}Y_0/Y_0}{X_jY_0/Y_0}. \tag{6}$$

Lemma 7 *For* $-1 \le j < \ell$, *we have* $X_j^* \lhd G$, $X_j^* = X_j(X_{j+1} \cap Y_0)$,

$$\frac{X_j^*}{X_j} \simeq \frac{X_{j+1} \cap Y_0}{X_j \cap Y_0}, \tag{7}$$

and

$$\frac{X_j^*}{X_{j+1} \cap Y_0} \simeq \frac{X_j}{X_j \cap Y_0}. \tag{8}$$

Proof Note that X_j^* is just $X_{j+1} \cap \pi_Y^{-1}(X_jY_0/Y_0) = X_{j+1} \cap X_jY_0$. Thus $X_j^* \lhd G$. Moreover, by the Dedekind Law (cf. Problem 2.49 of [16]), $X_{j+1} \cap X_jY_0 = X_j(X_{j+1} \cap Y_0)$, giving $X_j^* = X_j(X_{j+1} \cap Y_0)$. Thus X_j^* is just the cosets of X_j with representatives in $X_{j+1} \cap Y_0$, or as well the cosets of $X_{j+1} \cap Y_0$ with representatives in X_j. Applying Lemma 6 shows (7) and (8). •

Proposition 8 *We have* $X_{\ell-1}^* = X_{\ell-1}(X_\ell \cap Y_0) = X_{\ell-1}Y_0 = X_\ell$. *Also* $X_{-1}^* = X_{-1}(X_0 \cap Y_0) = X_0 \cap Y_0$.

Fix j, $-1 \le j < \ell - 1$. In the center of Figure 1, because of the isomorphism φ, we have

$$\frac{X_{j+1}Y_0/Y_0}{X_jY_0/Y_0} \simeq \frac{X_{j+2}/X_0}{X_{j+1}/X_0}. \tag{9}$$

On the right side of Figure 1, we can apply the correspondence theorem or third isomorphism theorem [16]. For example, we have

$$\frac{X_{j+2}/X_0}{X_{j+1}/X_0} \simeq \frac{X_{j+2}}{X_{j+1}}. \tag{10}$$

Using (6), (9), and (10), we conclude

$$\frac{X_{j+1}}{X_j^*} \simeq \frac{X_{j+2}}{X_{j+1}}. \tag{11}$$

Thus there is an isomorphism from X_{j+1}/X_j^* to X_{j+2}/X_{j+1}. Further we see there is a homomorphism from X_{j+1}/X_j to X_{j+2}/X_{j+1}.

Theorem 9 *If a group G has a shift structure $(\{X_j\}, Y_0, \varphi)$, then the chief series $\{X_j\}$ has a refinement given by*

$$\cdots \subset X_j \subset X_j^* \subset X_{j+1} \subset X_{j+1}^* \subset \cdots, \tag{12}$$

where each $X_j^* \lhd G$, such that

$$\frac{X_{j+1}}{X_j^*} \simeq \frac{X_{j+2}}{X_{j+1}} \tag{13}$$

for $-1 \leq j < \ell - 1$, where

$$X_j^* = X_j(X_{j+1} \cap Y_0) \tag{14}$$

for $-1 \leq j < \ell$. Note that $X_\ell / X_{\ell-1}^* \simeq \mathbf{1}$.

Proof This has been shown by (11) and Lemma 7. •

Remark: Note that $X_j^* = X_j$ if and only if $X_{j+1} \cap Y_0 = X_j \cap Y_0$, and in this case $|X_{j+1}|/|X_j| = |X_{j+2}|/|X_{j+1}|$. We have $X_{-1}^* = X_{-1}(X_0 \cap Y_0) = X_0 \cap Y_0$. Since $X_{\ell-1}Y_0 = G$, we have $X_{\ell-1}^* = X_{\ell-1}(X_\ell \cap Y_0) = G$. By definition of ℓ, we have $X_{\ell-1} << X_\ell = G$, and therefore $X_{\ell-1} << X_{\ell-1}^*$. (For groups A and B, we define $A >> B$ and $B << A$ if B is a strictly proper subgroup of A.)

Using the following lemma, we can refine the normal chain in (12) and collapse the tower of isomorphisms in (13) into X_0.

Lemma 10 *Let G be a group with a shift structure $(\{X_j\}, Y_0, \varphi)$. Fix j, $-1 \leq j < \ell - 1$. If there is a normal chain*

$$X_{j+1} = Q_{j+1}^0 \lhd Q_{j+1}^1 \lhd Q_{j+1}^2 \lhd \cdots \lhd Q_{j+1}^{p-1} \lhd Q_{j+1}^p = X_{j+2}, \tag{15}$$

then there is a normal chain

$$X_j \lhd Q_j^a \lhd \cdots \lhd Q_j^b \lhd Q_j^0 \lhd Q_j^1 \lhd Q_j^2 \lhd \cdots \lhd Q_j^{p-1} \lhd Q_j^p = X_{j+1}, \tag{16}$$

where $Q_j^0 = X_j^*$ and the normal chain

$$X_j \lhd Q_j^a \lhd \cdots \lhd Q_j^b \lhd Q_j^0 \tag{17}$$

is an arbitrary refinement of the trivial normal chain $X_j \lhd Q_j^0$. We have $X_j = Q_j^0$ if and only if $X_j = X_j^*$; in this case any refinement in (17) is trivial. Although there is no restriction on the choice of the normal chain in (17), there are dependent relations among the Q_j^n and Q_{j+1}^n, $0 \leq n \leq p$. We have

$$\frac{Q_j^n}{Q_j^m} \simeq \frac{Q_{j+1}^n}{Q_{j+1}^m} \tag{18}$$

for m, n satisfying $0 \leq m \leq n \leq p$. Moreover $Q_j^n \lhd G$ if $Q_{j+1}^n \lhd G$, for n satisfying $0 \leq n \leq p$. In addition, Q_j^n and Q_{j+1}^n are related by the isomorphism φ,

$$\varphi(Q_j^n Y_0/Y_0) = Q_{j+1}^n/X_0, \tag{19}$$

for n satisfying $0 \leq n \leq p$. For the normal chain in (17), we have

$$\varphi(X_j Y_0/Y_0) = \varphi(Q_j^a Y_0/Y_0) = \cdots = \varphi(Q_j^b Y_0/Y_0) = \varphi(Q_j^0 Y_0/Y_0) = X_{j+1}/X_0. \tag{20}$$

Conversely, if there is a normal chain as in (16) with $Q_j^0 = X_j^*$, then there is a normal chain as in (15), and $Q_{j+1}^n \lhd G$ if $Q_j^n \lhd G$, for n satisfying $0 \leq n \leq p$, and properties (18)-(20) hold.

Proof Fix j, $-1 \leq j < \ell - 1$. We first show that if (15) holds, then (16) holds. As in (15), let

$$Q_{j+1}^0 \lhd Q_{j+1}^1 \lhd Q_{j+1}^2 \lhd \cdots \lhd Q_{j+1}^p$$

be a normal chain with each $Q_{j+1}^n \lhd G$. We know $X_0 \lhd G$ and $X_0 \subset Q_{j+1}^0$. Then from the correspondence theorem, there is a normal chain

$$\frac{Q_{j+1}^0}{X_0} \lhd \frac{Q_{j+1}^1}{X_0} \lhd \frac{Q_{j+1}^2}{X_0} \lhd \cdots \lhd \frac{Q_{j+1}^p}{X_0}$$

where

$$\frac{Q_{j+1}^n/X_0}{Q_{j+1}^m/X_0} \simeq \frac{Q_{j+1}^n}{Q_{j+1}^m}, \tag{21}$$

for $m \geq 0, n \geq 0$ satisfying $0 \leq m \leq n \leq p$, and each $Q_{j+1}^n/X_0 \lhd G/X_0$.

Since $\varphi : G/Y_0 \to G/X_0$ is an isomorphism, for each n, $0 \leq n \leq p$, there is a subgroup $\dot{Q}_j^n/Y_0$ such that $\varphi(\dot{Q}_j^n/Y_0) = Q_{j+1}^n/X_0$. Thus the isomorphism φ gives a normal chain

$$\frac{\dot{Q}_j^0}{Y_0} \lhd \frac{\dot{Q}_j^1}{Y_0} \lhd \frac{\dot{Q}_j^2}{Y_0} \lhd \cdots \lhd \frac{\dot{Q}_j^p}{Y_0}, \tag{22}$$

where each $\dot{Q}_j^n/Y_0 \lhd G/Y_0$, and

$$\frac{\dot{Q}_j^n/Y_0}{\dot{Q}_j^m/Y_0} \simeq \frac{Q_{j+1}^n/X_0}{Q_{j+1}^m/X_0}. \tag{23}$$

Since G is a shift group, we have $\dot{Q}_j^0/Y_0 = X_j Y_0/Y_0$ and $\dot{Q}_j^p/Y_0 = X_{j+1}Y_0/Y_0$.

As before, consider the natural map $\pi_Y : G \to G/Y_0$ defined by $g \mapsto gY_0$, and its restriction $\pi_Y|X_{j+1}$. Define $Q_j^n \overset{\text{def}}{=} (\pi_Y|X_{j+1})^{-1}(\dot{Q}_j^n/Y_0)$. Then $Q_j^0 = X_j^*$ and $Q_j^p =$

X_{j+1}. Then using (22) and the correspondence theorem, we have a normal chain

$$Q_j^0 \lhd Q_j^1 \lhd Q_j^2 \lhd \cdots \lhd Q_j^p, \tag{24}$$

where

$$\frac{Q_j^n}{Q_j^m} \simeq \frac{\dot{Q}_j^n/Y_0}{\dot{Q}_j^m/Y_0}. \tag{25}$$

Since $Q_j^0 = X_j^*$, we have $X_j \subset Q_j^0$, and combining this with (24) gives (16). Note that $Q_j^n = X_{j+1} \cap \pi_Y^{-1}(\dot{Q}_j^n/Y_0)$, and thus each $Q_j^n \lhd G$. Collecting (21), (23), and (25) gives (18). Finally we have that $\varphi(\dot{Q}_j^n/Y_0) = Q_{j+1}^n/X_0$. But $(\pi_Y|X_{j+1})(Q_j^n) = \dot{Q}_j^n/Y_0$. This means $Q_j^n Y_0/Y_0 = \dot{Q}_j^n/Y_0$, giving (19).

Note that (20) holds since $X_j Y_0 = X_j^* Y_0$.

Now assume (16) holds. We can show that (15) holds by essentially reversing the above steps. •

We see there are two cases to consider in Lemma 10 depending on whether $X_j^* = X_j$ or $X_j^* >> X_j$. Formally, we introduce a parameter ε_j for $-1 \leq j < \ell$. We set $\varepsilon_j = 1$ if $X_j^* >> X_j$, and $\varepsilon_j = 0$ if $X_j^* = X_j$.

In the next theorem, we use Lemma 10 to find a refinement of (12). It is convenient to write the refinement using slightly different notation than in Lemma 10. Thus in place of (15), we write the portion of the refinement between X_{j+1} and X_{j+2} as

$$\begin{aligned} X_{j+1} = X_{j+1}^{(i_{j+1})} \lhd X_{j+1}^{(i_{j+1}+1)} \lhd X_{j+1}^{(i_{j+1}+2)} \lhd \cdots \\ \lhd X_{j+1}^{(\ell'-1)} \lhd X_{j+1}^{(\ell')} = X_{j+2}, \end{aligned} \tag{26}$$

where i_{j+1} and ℓ' are positive integers. Using (26) in Lemma 10, we obtain the portion of the refinement between X_j and X_{j+1} as

$$\begin{aligned} X_j \lhd X_j^{(i_{j+1})} \lhd X_j^{(i_{j+1}+1)} \lhd X_j^{(i_{j+1}+2)} \lhd \cdots \\ \lhd X_j^{(\ell'-1)} \lhd X_j^{(\ell')} = X_{j+1}, \end{aligned} \tag{27}$$

where $X_j^{(i_{j+1})} = X_j^*$. We only use Lemma 10 for a trivial refinement in (17), that is, when $X_j = Q_j^a = \cdots = Q_j^b$. In (27), we have $X_j^{(i_{j+1})} = X_j^*$ if $\varepsilon_j = 1$, and $X_j^{(i_{j+1})} = X_j^* = X_j$ if $\varepsilon_j = 0$.

In general for each j, $-1 \leq j \leq \ell - 1$, we define a refinement in which the superscript m of $X_j^{(m)}$ runs from integer i_j to integer ℓ'. For $0 \leq j \leq \ell$, we define $X_{j-1}^{(\ell')} \overset{\text{def}}{=} X_j \overset{\text{def}}{=} X_j^{(i_j)}$; then $X_{\ell-1}^{(\ell')} = X_\ell = X_\ell^{(i_\ell)}$. We also define $X_{-1} \overset{\text{def}}{=} X_{-1}^{(i_{-1})}$. In this notation, the portion of the refinement between X_j and X_{j+1} is

$$\begin{aligned} X_j = X_j^{(i_j)} \lhd X_j^{(i_j+1)} \lhd X_j^{(i_j+2)} \lhd \cdots \\ \lhd X_j^{(\ell'-1)} \lhd X_j^{(\ell')} = X_{j+1}. \end{aligned} \tag{28}$$

Comparing (27) and (28) shows that we must have $X_j = X_j^{(i_j)} = X_j^{(i_{j+1})} = X_j^*$ if $\varepsilon_j = 0$ and $X_j^{(i_j+1)} = X_j^{(i_{j+1})} = X_j^*$ if $\varepsilon_j = 1$. This means $i_j + \varepsilon_j = i_{j+1}$. If we use the above procedure and apply Lemma 10 recursively starting with the normal chain

$$X_{\ell-1} = X_{\ell-1}^{(i_{\ell-1})} \lhd X_{\ell-1}^{(\ell')} = X_\ell,$$

we obtain

$$i_j = \ell' - \sum_{j \leq i < \ell} \varepsilon_i \tag{29}$$

for $-1 \leq j < \ell$. Define

$$\ell' \overset{\text{def}}{=} \sum_{-1 \leq i < \ell} \varepsilon_i.$$

Then from (29) we see $i_{-1} = 0$. If $j = \ell$, we define $i_j = i_\ell \overset{\text{def}}{=} \ell'$ trivially. Thus as j runs from -1 to ℓ, i_j takes all values in the range $[0, \ell']$.

Theorem 11 *Let a group G have a shift structure $(\{X_j\}, Y_0, \varphi)$. There is a refinement of $\{X_j\}$, and of the normal chain in (12), given by*

$$\begin{aligned} X_{-1} = X_{-1}^{(i_{-1})} \lhd \cdots \lhd X_{-1}^{(\ell')} = X_0 = X_0^{(i_0)} \lhd \cdots \\ \lhd X_{j-1}^{(\ell')} = X_j = X_j^{(i_j)} \lhd X_j^{(i_j+1)} \lhd X_j^{(i_j+2)} \lhd \cdots \\ \lhd X_j^{(\ell'-1)} \lhd X_j^{(\ell')} = X_{j+1} = X_{j+1}^{(i_{j+1})} \lhd \cdots \\ \lhd X_{\ell-1}^{(i_{\ell-1})} \lhd X_{\ell-1}^{(i_{\ell-1}+1)} = X_{\ell-1}^{(\ell')} = X_\ell = X_\ell^{(i_\ell)}, \end{aligned} \tag{30}$$

where each $X_j^{(i_j+n)} \lhd G$ and $X_j^{(i_j+1)} = X_j^*$ if $\varepsilon_j = 1$. Moreover

$$\frac{X_{-1}^{(i_j+n)}}{X_{-1}^{(i_j+m)}} \simeq \frac{X_j^{(i_j+n)}}{X_j^{(i_j+m)}} \tag{31}$$

for $-1 \leq j < \ell$ and m, n satisfying $i_j \leq i_j + m \leq i_j + n \leq \ell'$. In addition, the isomorphism φ satisfies

$$\varphi(X_j^{(i_j+\varepsilon_j+n)} Y_0/Y_0) = X_{j+1}^{(i_{j+1}+n)}/X_0 \tag{32}$$

for $-1 \leq j < \ell$ and n satisfying $i_j + \varepsilon_j \leq i_j + \varepsilon_j + n \leq \ell'$. We have $\varphi(X_j^{(i_j)} Y_0/Y_0) = X_{j+1}^{(i_{j+1})}/X_0$ if $\varepsilon_j = 1$ or $\varepsilon_j = 0$, for $-1 \leq j < \ell$.

Proof Starting from the normal chain $X_{\ell-1} = X_{\ell-1}^{(i_{\ell-1})} \lhd X_{\ell-1}^{(\ell')} = X_\ell$, where $X_{\ell-1} \lhd G$ and $X_\ell \lhd G$, we can use Lemma 10 to go 'backwards' and for each j, $-1 \leq j < \ell - 1$, obtain a normal chain from X_j to X_{j+1} as in (30), where each $X_j^{(i_j+n)} \lhd G$ for n satisfying $i_j \leq i_j + n \leq \ell'$, and $X_j^{(i_j+1)} = X_j^*$ if $\varepsilon_j = 1$.

Since $i_{j+1} = i_j + \varepsilon_j$, we can restate (19) of Lemma 10 as in (32), for n satisfying $i_j + \varepsilon_j \leq i_j + \varepsilon_j + n \leq \ell'$.

It only remains to show (31). We can do this by induction. We assume (31) holds for $q + 1$, that is, we assume

$$\frac{X_{q+1}^{(i_j+n)}}{X_{q+1}^{(i_j+m)}} \simeq \frac{X_j^{(i_j+n)}}{X_j^{(i_j+m)}} \tag{33}$$

for $q+1 \le j < \ell$ and m, n satisfying $i_j \le i_j + m \le i_j + n \le \ell'$. Note that the left hand side of (33) is well defined since $i_{q+1} \le i_j$ for $q+1 \le j$. Then we show (31) holds for q, that is, we show

$$\frac{X_q^{(i_j+n)}}{X_q^{(i_j+m)}} \simeq \frac{X_j^{(i_j+n)}}{X_j^{(i_j+m)}} \tag{34}$$

for $q \le j < \ell$ and m, n satisfying $i_j \le i_j + m \le i_j + n \le \ell'$.

Assume that j satisfies $q+1 \le j < \ell$ and m, n satisfy $i_j \le i_j + m \le i_j + n \le \ell'$. Assume that (33) holds. We can write the portion of the normal chain in (30) between X_q and X_{q+1} as

$$X_q = X_q^{(i_q)} \lhd X_q^{(i_q+1)} \lhd X_q^{(i_q+2)} \lhd \cdots \lhd X_q^{(\ell'-1)} \lhd X_q^{(\ell')} = X_{q+1}, \tag{35}$$

and between X_{q+1} and X_{q+2} as

$$X_{q+1} = X_{q+1}^{(i_{q+1})} \lhd X_{q+1}^{(i_{q+1}+1)} \lhd X_{q+1}^{(i_{q+1}+2)} \lhd \cdots \lhd X_{q+1}^{(\ell'-1)} \lhd X_{q+1}^{(\ell')} = X_{q+2}. \tag{36}$$

Then using Lemma 10 with (36) in place of (15) and (35) in place of (16), we have from (18)

$$\frac{X_q^{(i_j+n)}}{X_q^{(i_j+m)}} \simeq \frac{X_{q+1}^{(i_j+n)}}{X_{q+1}^{(i_j+m)}}. \tag{37}$$

Note that all terms in (37) are well defined since $i_q \le i_{q+1} \le i_j$ for $q+1 \le j$. Combining (37) with (33) gives

$$\frac{X_q^{(i_j+n)}}{X_q^{(i_j+m)}} \simeq \frac{X_j^{(i_j+n)}}{X_j^{(i_j+m)}}. \tag{38}$$

We know that (38) holds for $q+1 \le j < \ell$ and m, n satisfying $i_j \le i_j + m \le i_j + n \le \ell'$. But (38) also holds trivially for $j = q$. Then (38) holds for $q \le j < \ell$ and m, n satisfying $i_j \le i_j + m \le i_j + n \le \ell'$, giving (34).

We start the induction by proving (34) for $q = \ell - 2$. But from Theorem 9 or Lemma 10, we know there are normal chains $X_{\ell-1} \lhd X_\ell$ and $X_{\ell-2} \lhd X_{\ell-2}^* \lhd X_{\ell-1}$ with

$$\frac{X_{\ell-1}}{X_{\ell-2}^*} \simeq \frac{X_\ell}{X_{\ell-1}}.$$

Rewriting this as

$$\frac{X_{\ell-2}^{(\ell')}}{X_{\ell-2}^{(i_{\ell-1})}} \simeq \frac{X_{\ell-1}^{(\ell')}}{X_{\ell-1}^{(i_{\ell-1})}}$$

gives (34) for $q = \ell - 2$. •

We illustrate Theorem 11 in Figure 2. In the example shown, we have $\varepsilon_{j+1} = 0$ and $\varepsilon_j = 1$. Then if we let $i_{j+2} = i+1$, we have $i_{j+1} = i+1$ and $i_j = i$. For this example then, we have $X_{j+1}^{(i+1)} = X_{j+1}^* = X_{j+1}$ and $X_j^{(i+1)} = X_j^* >> X_j$. Note that the quotient groups formed by entries at the intersection of each column of the same two rows are isomorphic. For example,

$$\frac{X_{-1}^{(\ell'-1)}}{X_{-1}^{(i+2)}} \simeq \frac{X_j^{(\ell'-1)}}{X_j^{(i+2)}} \simeq \frac{X_{j+1}^{(\ell'-1)}}{X_{j+1}^{(i+2)}} \simeq \frac{X_{j+2}^{(\ell'-1)}}{X_{j+2}^{(i+2)}}.$$

Figure 2 is reminiscent of the shift register structure used to realize strongly controllable group codes [2, 3].

$$\begin{array}{llllllll}
X_{-1}^{(\ell')} & \cdots & X_j^{(\ell')} & X_{j+1}^{(\ell')} & X_{j+2}^{(\ell')} & \cdots & X_{\ell-1}^{(\ell')} & X_\ell^{(\ell')} \\
X_{-1}^{(\ell'-1)} & \cdots & X_j^{(\ell'-1)} & X_{j+1}^{(\ell'-1)} & X_{j+2}^{(\ell'-1)} & \cdots & X_{\ell-1}^{(\ell'-1)} & \\
\vdots & & \vdots & \vdots & \vdots & & & \\
X_{-1}^{(i+2)} & \cdots & X_j^{(i+2)} & X_{j+1}^{(i+2)} & X_{j+2}^{(i+2)} & \cdots & & \\
X_{-1}^{(i+1)} & \cdots & X_j^{(i+1)} & X_{j+1}^{(i+1)} & X_{j+2}^{(i+1)} & & & \\
X_{-1}^{(i)} & \cdots & X_j^{(i)} & & & & & \\
\vdots & & & & & & & \\
X_{-1}^{(0)} & & & & & & &
\end{array}$$

Figure 2: Illustration of Theorem 11.

We are particularly interested in the portion of the normal chain from X_{-1} to X_0:

$$X_{-1} = X_{-1}^{(i_{-1})} \lhd X_{-1}^{(i_{-1}+1)} \lhd \cdots \lhd X_{-1}^{(i_{-1}+n)} \lhd \cdots \lhd X_{-1}^{(\ell'-1)} \lhd X_{-1}^{(\ell')} = X_0. \tag{39}$$

In (39), the superscript m of $X_{-1}^{(m)}$ takes all values in the interval $[i_{-1}, \ell']$ or $[0, \ell']$. Using (29), for j satisfying $-1 \le j \le \ell$, we know i_j takes all values in the interval $[0, \ell']$. Then for $-1 \le j \le \ell$, the term $X_{-1}^{(i_j)}$ appears in (39), and we can make the definition

$$\Delta_j \overset{\text{def}}{=} X_{-1}^{(i_j)}.$$

Then

$$X_{-1} = \Delta_{-1} \lhd \Delta_0 \lhd \cdots \lhd \Delta_j \lhd \cdots \lhd \Delta_{\ell-1} \lhd \Delta_\ell = X_0 \tag{40}$$

is a refinement of (39) which at most just repeats terms in (39). Since each $X_{-1}^{(i_{-1}+n)} \lhd G$, we know that each $\Delta_j \lhd G$.

Given the shift structure $(\{X_j\}, Y_0, \varphi)$ of a shift group G, the normal chain in (30) is uniquely determined, and so the normal chains (39) and (40) are uniquely determined. We say the normal chain in (40) is a *signature chain* of shift group G. Also, given the shift structure of a shift group G, we can form the intersection group $X_j \cap Y_0$ for each j, and this gives the normal chain

$$\mathbf{1} = (X_{-1} \cap Y_0) \subset (X_0 \cap Y_0) \subset (X_1 \cap Y_0) \subset \cdots (X_{\ell-1} \cap Y_0) \subset (X_\ell \cap Y_0) = Y_0, \tag{41}$$

where each $X_j \cap Y_0 \lhd G$. We say the normal chain in (41) is a *cosignature chain* of shift group G. The cosignature chain is also uniquely determined by the shift structure of a shift group.

We now give some properties of the signature and cosignature chain.

Theorem 12 *Let group G have a shift structure $(\{X_j\}, Y_0, \varphi)$. Fix j, $-1 \leq j < \ell$. The signature chain has the property that*

$$\frac{X_{j+1}}{X_j} \simeq \frac{X_0}{\Delta_j}, \tag{42}$$

$$\frac{X_{j+1}}{X_j^*} \simeq \frac{X_0}{\Delta_{j+1}}, \tag{43}$$

and

$$\frac{X_j^*}{X_j} \simeq \frac{\Delta_{j+1}}{\Delta_j}. \tag{44}$$

The cosignature chain has the property that

$$\frac{X_jY_0}{X_j} \simeq \frac{Y_0}{X_j \cap Y_0}, \tag{45}$$

$$\frac{X_{j+1}Y_0}{X_{j+1}} \simeq \frac{Y_0}{X_{j+1} \cap Y_0}, \tag{46}$$

$$\frac{X_j^*}{X_j} \simeq \frac{X_{j+1} \cap Y_0}{X_j \cap Y_0}, \tag{47}$$

and

$$\frac{X_jY_0}{X_j^*} \simeq \frac{X_{j+1}Y_0}{X_{j+1}} \simeq \frac{Y_0}{X_{j+1} \cap Y_0}, \tag{48}$$

where (45)-(47) are analogous to (42)-(44). Lastly, we have

$$\Delta_0 = X_{-1}^* = X_0 \cap Y_0, \tag{49}$$

$$\frac{\Delta_{j+1}}{\Delta_j} \simeq \frac{X_{j+1} \cap Y_0}{X_j \cap Y_0}, \tag{50}$$

and

$$|\Delta_{j+1}| = |X_{j+1} \cap Y_0|. \tag{51}$$

Proof Results (42)-(44) follow from (31) of Theorem 11 using the definition of Δ_j.

Results (45) and (46) follow from the second isomorphism theorem, and result (47) follows from (7) of Lemma 7. But we know

$$\frac{X_jY_0}{X_j^*} = \frac{X_j^*Y_0}{X_j^*} \simeq \frac{Y_0}{X_j^* \cap Y_0} = \frac{Y_0}{X_{j+1} \cap Y_0} \simeq \frac{X_{j+1}Y_0}{X_{j+1}},$$

giving (48).

We now show (49). We have $X_{-1}^{(i_{-1}+1)} = X_{-1}^*$ if $\varepsilon_{-1} = 1$, and $X_{-1}^{(i_{-1})} = X_{-1}^* = X_{-1}$ if $\varepsilon_{-1} = 0$. Also i_0 and i_{-1} are related by $i_0 = i_{-1} + \varepsilon_{-1}$. Thus $X_{-1}^{(i_0)} = X_{-1}^*$ if $\varepsilon_{-1} = 1$ or $\varepsilon_{-1} = 0$. But $\Delta_0 = X_{-1}^{(i_0)}$ and $X_{-1}^* = X_0 \cap Y_0$; then (49) follows. We have (50) holds using (44) and (47). Now use induction with (49) and (50) to obtain (51). •

Remark: Note from (50) that if $\Delta_{-1} = \cdots = \Delta_j = \mathbf{1}$ and $\Delta_{j+1} \neq \mathbf{1}$, then $X_0 \cap Y_0 = \cdots = X_j \cap Y_0 = \mathbf{1}$ and $\Delta_{j+1} \simeq X_{j+1} \cap Y_0$. Since $X_{\ell-1} << X_{\ell-1}^*$, we always have $|\Delta_{\ell-1}| < |\Delta_\ell|$.

Corollary 13 *Assume G is a shift group with shift structure $(\{X_j\}, Y_0, \varphi)$. The factor groups of the signature chain $\{\Delta_j\}$ are isomorphic to the factor groups of the cosignature chain $\{X_j \cap Y_0\}$ in 1-1 order, i.e., as in (50). The signature chain $\{\Delta_j\}$ is a composition series of X_0 if and only if the cosignature chain $\{X_j \cap Y_0\}$ is a composition series of Y_0. The signature chain $\{\Delta_j\}$ is a solvable series of X_0 (meaning factor groups are abelian) if and only if the cosignature chain $\{X_j \cap Y_0\}$ is a solvable series of Y_0.*

Proof We prove the second statement: a normal series is a composition series if and only if its factor groups are either simple or trivial (cf. Problem 5.7 of [16]). •

Loeliger and Mittelholzer give an example of a shift group in which $X_0 \simeq \mathbf{Z}_2 \times \mathbf{Z}_2$ and $Y_0 \simeq \mathbf{Z}_4$, with $\Delta_0 = X_0 \cap Y_0 = \mathbf{Z}_2$ (cf. Example 3.2 of [3]). Even though X_0 and Y_0 are not isomorphic, it can be verified that the results in Corollary 13 hold.

We have the following easy corollary of Theorem 12.

Corollary 14 *If G is a group with a shift structure $(\{X_j\}, Y_0, \varphi)$, the factor groups X_{j+1}/X_j in the normal chain $\{X_j\}$ are abelian if X_0 is abelian. In this case then, $\{X_j\}$ is a solvable series and G is solvable.*

We show the relevance of this corollary in the next section.

We now generalize Theorem 11 and Corollary 14. In the next theorem, we find a refinement of (30) using Lemma 10. As before, it is convenient to write the refinement using slightly different notation than in Lemma 10. Thus in place of (15), we write the portion of the refinement between X_{j+1} and X_{j+2} as

$$X_{j+1} = \hat{X}_{j+1}^{(r_{j+1})} \lhd \hat{X}_{j+1}^{(r_{j+1}+1)} \lhd \hat{X}_{j+1}^{(r_{j+1}+2)} \lhd \cdots \lhd \hat{X}_{j+1}^{(\kappa-1)} \lhd \hat{X}_{j+1}^{(\kappa)} = X_{j+2}, \tag{52}$$

where r_{j+1} and κ are positive integers. Using (52) in Lemma 10, we obtain the portion of the refinement between X_j and X_{j+1} as

$$X_j \lhd Q_j^a \lhd \cdots \lhd Q_j^b \lhd \hat{X}_j^{(r_{j+1})} \lhd \hat{X}_j^{(r_{j+1}+1)} \lhd \hat{X}_j^{(r_{j+1}+2)} \lhd \cdots \lhd \hat{X}_j^{(\kappa-1)} \lhd \hat{X}_j^{(\kappa)} = X_{j+1}, \tag{53}$$

where $\hat{X}_j^{(r_{j+1})} = X_j^*$. In this case, we use Lemma 10 for a nontrivial refinement in (17); in fact we select

$$X_j \lhd Q_j^a \lhd \cdots \lhd Q_j^b \lhd \hat{X}_j^{(r_{j+1})}$$

to be a composition chain of $X_j \lhd \hat{X}_j^{(r_{j+1})}$. In (53), we have $\hat{X}_j^{(r_{j+1})} = X_j^*$ if $\varepsilon_j = 1$, and $\hat{X}_j^{(r_{j+1})} = X_j^* = X_j$ if $\varepsilon_j = 0$.

In general for each j, $-1 \le j \le \ell - 1$, we define a refinement in which the superscript m of $\hat{X}_j^{(m)}$ runs from integer r_j to integer κ. For $0 \le j \le \ell$, we define $\hat{X}_{j-1}^{(\kappa)} \overset{\text{def}}{=} X_j \overset{\text{def}}{=} \hat{X}_j^{(r_j)}$; then $\hat{X}_{\ell-1}^{(\kappa)} = X_\ell = \hat{X}_\ell^{(r_\ell)}$. We also define $X_{-1} \overset{\text{def}}{=} \hat{X}_{-1}^{(r_{-1})}$. In this notation, the portion of the refinement between X_j and X_{j+1} is

$$\begin{aligned} X_j = \hat{X}_j^{(r_j)} \lhd \hat{X}_j^{(r_j+1)} \lhd \hat{X}_j^{(r_j+2)} \lhd \cdots \\ \lhd \hat{X}_j^{(r_j+\delta_j-1)} \lhd \hat{X}_j^{(r_j+\delta_j)} \lhd \cdots \\ \lhd \hat{X}_j^{(\kappa-1)} \lhd \hat{X}_j^{(\kappa)} = X_{j+1}. \quad (54) \end{aligned}$$

Comparing (53) and (54) shows that we must have $X_j = \hat{X}_j^{(r_j)} = \hat{X}_j^{(r_{j+1})} = X_j^*$ if $\varepsilon_j = 0$. If $\varepsilon_j = 1$, there is an integer parameter $\delta_j > 0$ such that $\hat{X}_j^{(r_j+\delta_j)} = \hat{X}_j^{(r_{j+1})} = X_j^*$. This means $r_j + \delta_j = r_{j+1}$ if $\varepsilon_j = 1$. If $\varepsilon_j = 0$, so that $r_j = r_{j+1}$, we set $\delta_j \overset{\text{def}}{=} 0$. If we use the above procedure and apply Lemma 10 recursively starting with the normal chain

$$\begin{aligned} X_{\ell-1} = \hat{X}_{\ell-1}^{(r_{\ell-1})} \lhd \hat{X}_{\ell-1}^{(r_{\ell-1}+1)} \lhd \cdots \lhd \hat{X}_{\ell-1}^{(r_{\ell-1}+\delta_{\ell-1}-1)} \\ \lhd \hat{X}_{\ell-1}^{(r_{\ell-1}+\delta_{\ell-1})} = \hat{X}_{\ell-1}^{(\kappa)} = X_\ell, \end{aligned}$$

a composition chain of $X_{\ell-1} \lhd X_\ell$, we obtain

$$r_j = \kappa - \sum_{j \le i < \ell} \delta_i \qquad (55)$$

for $-1 \le j < \ell$. Define

$$\kappa \overset{\text{def}}{=} \sum_{-1 \le i < \ell} \delta_i.$$

Then from (55) we see $r_{-1} = 0$. If $j = \ell$, we define $r_j = r_\ell \overset{\text{def}}{=} \kappa$ trivially. Thus as j runs from -1 to ℓ, r_j takes values in the range $[0, \kappa]$.

Theorem 15 *Let a group G have a shift structure $(\{X_j\}, Y_0, \varphi)$. There is a refinement of $\{X_j\}$, and of the normal chain $\{X_j^{(i_j+n')}\}$ in (30), given by*

$$\begin{aligned} X_{-1} = \hat{X}_{-1}^{(r_{-1})} \lhd \cdots \lhd \hat{X}_{-1}^{(\kappa)} = X_0 = \hat{X}_0^{(r_0)} \lhd \cdots \\ \lhd \hat{X}_{j-1}^{(\kappa)} = X_j = \hat{X}_j^{(r_j)} \lhd \hat{X}_j^{(r_j+1)} \lhd \hat{X}_j^{(r_j+2)} \lhd \cdots \\ \lhd \hat{X}_j^{(\kappa-1)} \lhd \hat{X}_j^{(\kappa)} = X_{j+1} = \hat{X}_{j+1}^{(r_{j+1})} \lhd \cdots \\ \lhd \hat{X}_{\ell-1}^{(r_{\ell-1})} \lhd \hat{X}_{\ell-1}^{(r_{\ell-1}+1)} = \hat{X}_{\ell-1}^{(\kappa)} = X_\ell = \hat{X}_\ell^{(r_\ell)}, \quad (56) \end{aligned}$$

where $\hat{X}_j^{(r_j+\delta_j)} = X_j^*$ if $\varepsilon_j = 1$. The normal chain (56) is a composition series of G. Moreover

$$\frac{\hat{X}_{-1}^{(r_j+n+1)}}{\hat{X}_{-1}^{(r_j+n)}} \simeq \frac{\hat{X}_j^{(r_j+n+1)}}{\hat{X}_j^{(r_j+n)}}$$

for $-1 \le j < \ell$ and n satisfying $r_j \le r_j + n < \kappa$. In addition, the isomorphism φ satisfies

$$\varphi(\hat{X}_j^{(r_j+\delta_j+n)} Y_0/Y_0) = \hat{X}_{j+1}^{(r_{j+1}+n)}/X_0 \qquad (57)$$

for $-1 \le j < \ell$ and n satisfying $r_j + \delta_j \le r_j + \delta_j + n \le \kappa$. We have

$$\varphi(\hat{X}_j^{(r_j+n)} Y_0/Y_0) = \hat{X}_{j+1}^{(r_{j+1})}/X_0$$

for $-1 \le j < \ell$ and $n = 0, \ldots, \delta_j - 1$. The term $X_j^{(i_j+n')}$ in (30), $n' = 0, \ldots, \ell' - i_j$, is the term $\hat{X}_j^{(r_j+n)}$ in the refinement (56), where $n = \sum_{j \le i < j+n'} \delta_i$.

Proof The proof is similar to the proof of Theorem 11. •

Corollary 16 *Let a group G have a shift structure $(\{X_j\}, Y_0, \varphi)$. Then G is solvable if and only if X_0 is solvable.*

Proof If G is solvable, then every subgroup is solvable, so X_0 is solvable. For the converse result, note that we can construct a figure like Figure 2. Going backwards, first find a normal chain from $X_{\ell-1}$ to X_ℓ for which factor groups are simple. By Lemma 10, there is a chain from $X_{\ell-2}^*$ to $X_{\ell-1}$ with the same factor groups. Now find a chain from $X_{\ell-2}$ to $X_{\ell-2}^*$ for which factor groups are simple. This gives a chain from $X_{\ell-2}$ to $X_{\ell-1}$ with simple factor groups. Continue in this way to X_0. Then there is a chain from X_{-1}^* to X_0 for which factor groups are simple. Now find a chain from X_{-1} to X_{-1}^* for which factor groups are simple. This gives a chain for X_0 in which all factor groups are simple, i.e., this is a composition chain of X_0. But if X_0 is solvable, then this composition chain must have primary cyclic factor groups. Going in reverse, this implies that factor groups of chain from X_j to X_{j+1} are primary cyclic, for $0 \le j < \ell$. This implies G is solvable. •

Since $G = X_{\ell-1}Y_0$ has normal subgroup X_0Y_0, we can regard G as like a wreath product with base group X_0Y_0.

We illustrate some of the results in this section in Figure 3. The group $G = X_{\ell-1}Y_0$ is composed of cosets of X_0Y_0, and also cosets of X_0 and cosets of Y_0. For $j = 0, \ldots \ell - 1$, the normal subgroup X_jY_0 is composed of cosets of X_0Y_0, and also cosets of X_0 and Y_0. In Figure 3, we draw G and X_jY_0 as a group of cosets of Y_0, with Y_0 laid along the vertical axis. We have $|X_jY_0| = |X_j||Y_0|/|X_j \cap Y_0|$. Thus in Figure 3, X_jY_0 has a 'height' of $|Y_0|$ and a 'width' of $|X_j|/|X_j \cap Y_0|$. Note that we have

$$\begin{aligned} |X_j| &= |X_0| \prod_{k=1}^{j} \frac{|X_k|}{|X_{k-1}|} \\ &= \frac{|X_0|^{j+1}}{|\Delta_{j-1}| \cdots |\Delta_0|}. \end{aligned}$$

Thus the signature chain or cosignature chain determines $|X_j|$ and $|X_jY_0|$. Using Figure 3, it is easy to visualize many of the results in Theorems 9 and 12. The following is clear from the structure of G and $\mathcal{G}_G$ (see also [2, 3]).

Proposition 17 *A coset of X_0 and a coset of Y_0 are disjoint unless they are in the the same coset of X_0Y_0, in which case they have $|X_0 \cap Y_0|$ elements in common.*

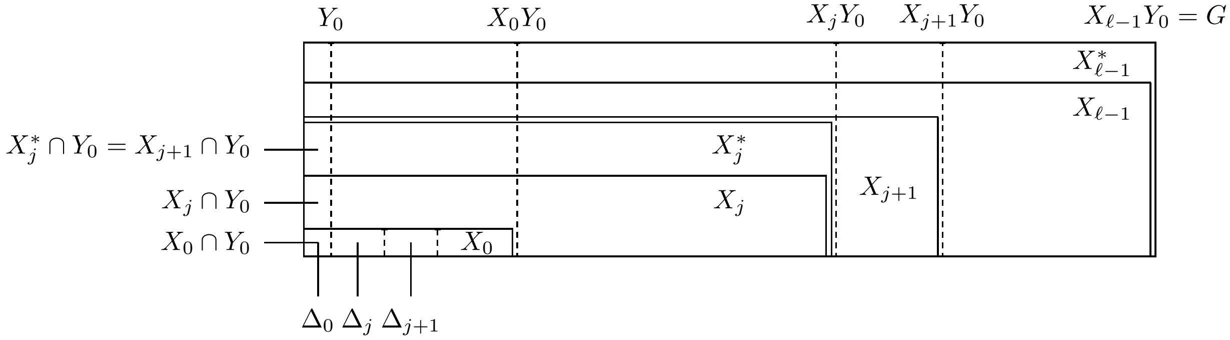

Figure 3: Diagram of shift group G with shift structure $(\{X_j\}, Y_0, \varphi)$.

3 Group codes

Trott and Sarvis speculated there might be a connection between a homogeneous trellis code, Latin square, and translation net [8, 9]. In this section, we show such a connection for a group code, the most important example of a homogeneous trellis code.

Let $\mathcal{G}$ be any graph. We define a *labeled graph* $(\mathcal{G}, \mathcal{L})$ as a graph $\mathcal{G}$ and a mapping $\mathcal{L} : \mathcal{E} \to A$ where A is an *alphabet.* Let B be a group, and let $\mathcal{G}_B$ be a graph constructed as in Section 2 using $\mathcal{E} = B$ and $\mathcal{V} = B/B^+$, where $B^+ \lhd B$. We define a *group code* as a labeled graph $(\mathcal{G}_B, \omega)$ where ω is a homomorphism $\omega : \mathcal{E} \to A$ and alphabet A is a group; this is essentially the definition used in [3]. We say the group code is ℓ-controllable if graph $\mathcal{G}_B$ is ℓ-controllable. In particular, here we consider a group G with a shift structure $(\{X_j\}, Y_0, \varphi)$. Then graph $\mathcal{G}_G$, formed using $\mathcal{E} = G$ and $\mathcal{V} = G/X_0$, is ℓ-controllable and group code $(\mathcal{G}_G, \omega)$ is ℓ-controllable. We only consider the case $|X_0 \cap Y_0| = 1$ where there are no multiple edges. If $|X_0 \cap Y_0| > 1$, the discussion below can be applied to quotient group $G/X_0 \cap Y_0$.

Since $X_0 \cap Y_0 = \mathbf{1}$, and $X_0 \lhd G$, $Y_0 \lhd G$, we have $X_0Y_0 \simeq X_0 \times Y_0$. From Definition 1, we know that $|X_0| = |Y_0|$. Thus it is natural to think of X_0Y_0 as a *square* whose rows are $\{gX_0 | g \in X_0Y_0\}$ and columns are $\{gY_0 | g \in X_0Y_0\}$. The elements of row gX_0 are edges that split from state gX_0 in G/X_0. The elements of column gY_0 are edges that merge to state $\varphi(gY_0)$ in G/X_0. In G/X_0Y_0, we can think of coset hX_0Y_0 as a square. The rows of the square are $\{gX_0 | g \in hX_0Y_0\}$; elements in gX_0 split from state gX_0. The columns of the square are $\{gY_0 | g \in hX_0Y_0\}$; elements in gY_0 merge to state $\varphi(gY_0)$. Proposition 17 shows that a row and column do not intersect unless they are from the same square, in which case they intersect once. If we regard $\mathcal{G}_G$ as a trellis section, such squares are often called subtrellises [8].

Suppose we can form a group code in which all squares can be labeled so they are *Latin squares.* In this case, the edges that split from any state all have different labels, and the edges that merge to any state all have different labels. This type of labeling is useful in practical trellis codes [4, 5, 6, 7, 8]. We call such a group code a *Latin group code.* Again it is to be understood that the term Latin group code means the Latin squares are formed using squares defined as above. Also it is understood the shift group G of a Latin group code has $|X_0 \cap Y_0| = 1$.

In a Latin group code, since ω is a homomorphism $\omega : G \to A$, we must have the assignment $\omega : X_0Y_0 \mapsto A_0$, where $A_0 \lhd A$ and $|A_0| = |X_0|$. Given a coset gA_0 of A_0, all squares in $\omega^{-1}(gA_0)$ have the same labels, and we call this collection of Latin squares a *Latin clique.* Assume there are q Latin cliques in $\mathcal{G}$, called $C_0, \ldots C_{q-1}$; then $|A|/|A_0| = q$. We define $\omega^{-1}(A_0) \overset{\text{def}}{=} G_0$; this gives $G_0 \lhd G$. We assume that G_0 is the stabilizer of squares in Latin clique C_0. Let a be the identity of A. Let G_a be the kernel of ω, or $G_\mathsf{a} = \omega^{-1}(\mathsf{a})$. Then $G_\mathsf{a} \lhd G$, and ω is essentially the natural map with kernel G_a, or essentially $\omega' : G \to G/G_\mathsf{a}$ with $G/G_\mathsf{a} \simeq A$. Without loss of generality, we can assume that label a is used in Latin clique C_0. Then $G_\mathsf{a} \subset G_0$.

Let $\Box_0$ be the Latin square of square X_0Y_0; assume $\Box_0 \subset C_0$. We can think of $\Box_0$ as a finite geometry F with three parallel classes of lines. The first class are the rows $\{gX_0 | g \in X_0Y_0\}$ of X_0Y_0; the second class are the columns $\{gY_0 | g \in X_0Y_0\}$ of X_0Y_0. The third parallel class consists of lines formed by entries in $\Box_0$ with the same label. For example, line l_a consists of all entries in $\Box_0$ with label a. Without loss of generality, we can assume that line l_a includes the identity entry, i.e., the label of $\mathbf{1}$ is a. Note that lines from the same class do not intersect, and using Proposition 17, lines from different classes intersect exactly once. Thus $\Box_0$ is a (t, s) net for $s = 3$, where $t = |X_0|$.

We define an action of G on itself by the product gG for each $g \in G$. In this sense, X_0Y_0 acts transitively, in fact regularly, on the entries in square X_0Y_0. In fact, because there is a homomorphism $\omega : G \to A$, X_0Y_0 must also be a translation group of Latin square $\Box_0$, and so $\Box_0$ must be a translation $(t, 3)$ net.

From the theory of Latin squares [18], a finite geometry F that is a $(t, 3)$ net is a translation $(t, 3)$ net if and only if F has a translation group Q which has a *partial congruence partition* (PCP): three subgroups W_1, W_2, W_3 such that $W_i \cap W_j = \mathbf{1}$ and $W_iW_j = Q$ for $1 \le i, j \le 3$, $i \ne j$. In this case, W_i acts regularly on lines in the i^{th} parallel class of the $(t, 3)$ net, $1 \le i \le 3$. In general F

may have more than one translation group, and a given translation group Q may have more than one PCP [21].

We already know that $\Box_0$ has translation group X_0Y_0. But any PCP in X_0Y_0 must have $W_1 = X_0$ and $W_2 = Y_0$ because the only subgroup of G which acts regularly on a row of $\Box_0$ is X_0, and the only subgroup which acts regularly on a column of $\Box_0$ is Y_0. Thus $\Box_0$ can be a translation $(t, 3)$ net if and only if there is some subgroup $W_3 \subset X_0Y_0$ which forms a PCP with $W_1 = X_0$ and $W_2 = Y_0$. But W_3 must necessarily be the stabilizer of line l_{a}, or $G_{\mathsf{a}} \cap X_0Y_0 \overset{\text{def}}{=} K_{\mathsf{a}}$. Thus $\Box_0$ is a translation $(t, 3)$ net if and only if $X_0 \cap K_{\mathsf{a}} = Y_0 \cap K_{\mathsf{a}} = \mathbf{1}$ and $X_0K_{\mathsf{a}} = Y_0K_{\mathsf{a}} = X_0Y_0$.

We now digress briefly to discuss the work of Sprague [21], Mann [19], and Bailey and Jungnickel [22] (see also [18]).

Theorem 18 (Sprague) *Let* $\mathbf{W} = \{W_1, \ldots W_s\}$ *be a* (t, s) *PCP in* Q*. Then the following assertions hold:*

(1) If W_1 *is a normal subgroup of* Q*, then* $W_2 \simeq \cdots \simeq W_s$*.*

(2) If W_1 *and* W_2 *are normal subgroups of* Q*, then one has* $Q \simeq W_1 \times W_2$ *and* $W_1 \simeq W_2 \simeq \cdots \simeq W_s$*.*

(3) If $\mathbf{W}$ *has 3 normal components, then* Q *is abelian.*

Given a group H and an automorphism θ of H, we can construct a Latin square *based on* H. The point set is $H \times H$; the rows are $\{(h, 1) | h \in H\}$; the columns are $\{(1, h) | h \in H\}$; and the letters are the sets $\{(h_1, h_2) | h_1(\theta(h_2)) = k\}$ for elements k of H. We call this the Latin square based on H constructed by the *automorphism method* of Mann [19]. Define a set Σ of automorphisms of H to be *fixed point free* if $\theta\sigma^{-1}$ is fixed point free for every distinct pair of elements θ, σ of Σ.

Theorem 19 (Bailey and Jungnickel) *Let* H *be a group of order* t*, and let* Σ *be a fixed point free set of* s' *automorphisms of* H*. Put* $Q = H \times H$*. For* θ *in* Σ*, put* $W_\theta = \{(h, \theta(h)) | h \in H\}$*, and put* $W_0 = \mathbf{1} \times H$ *and* $W_\infty = H \times \mathbf{1}$*. Then* $\{W_0, W_\infty\} \cup \{W_\theta | \theta \in \Sigma\}$ *is a* $(t, s' + 2)$ *PCP for* Q *with normal components* W_0 *and* W_∞*. Conversely, every* $(t, s' + 2)$ *PCP with two normal components may be represented in this way.*

This theorem shows that a fixed point free set of s' automorphisms of H gives rise to a set of s' mutually orthogonal Latin squares based on H. When H is elementary abelian, this method gives complete sets of mutually orthogonal Latin squares based on H, that is, $s' = t - 1$ [22].

We now use these results in our discussion. We know something more about the translation group of X_0Y_0. We have $X_0 \lhd X_0Y_0$ and $Y_0 \lhd X_0Y_0$. Then from Theorem 18, we must have $X_0 \simeq Y_0 \simeq K_{\mathsf{a}}$. In fact from Theorem 19, K_{a} can be explicitly determined as

$$K_{\mathsf{a}} = \{x(\mu \circ \theta(x)) | x \in X_0,\ \mu \circ \theta : X_0 \to Y_0\}, \tag{58}$$

where θ is an automorphism of X_0 and μ is an isomorphism from X_0 to Y_0, $X_0 \overset{\mu}{\simeq} Y_0$. Thus each distinct composition $\mu \circ \theta : X_0 \to Y_0$ gives a different K_{a}. Thus $\Box_0$ can be a translation $(t, 3)$ net if and only if there is an isomorphism $X_0 \simeq Y_0$.

Further, since $K_{\mathsf{a}} = G_{\mathsf{a}} \cap X_0Y_0$, then $K_{\mathsf{a}} \lhd G$ and $K_{\mathsf{a}} \lhd X_0Y_0$. Then we know from Theorem 18 that X_0Y_0 must be abelian, and since $X_0Y_0 \simeq X_0 \times Y_0$, both X_0 and Y_0 must be abelian. Note that the possible isomorphisms $X_0 \simeq Y_0$ are well known when X_0 is abelian [16].

Theorem 20 *The shift group* G *of an* ℓ*-controllable Latin group code* $(\mathcal{G}_G, \omega)$ *has* $X_0 \cap Y_0 = \mathbf{1}$*,* $X_0 \simeq Y_0$*, and* X_0, Y_0 *abelian.*

Corollary 21 *The shift group* G *of an* ℓ*-controllable Latin group code* $(\mathcal{G}_G, \omega)$ *is a solvable group and* $\{X_j\}$ *is a solvable series.*

Proof Use Corollary 14. •

Theorem 22 *The Latin squares* $\Box_0$ *which can appear in an* ℓ*-controllable Latin group code* $(\mathcal{G}_G, \omega)$ *are exactly those based on* X_0 *constructed by the automorphism method of Mann, where* X_0 *is abelian.*

Proof The construction in (58) gives Latin squares constructed by the automorphism method of Mann [22]. •

The Sarvis conjecture is that each fully connected subtrellis of a homogeneous Latin trellis corresponds to a principal isotope of a group Latin square [9]; this is equivalent to the conjecture that $\Box_0$ is the principal isotope of a group Latin square [8]. Theorem 22 shows the Sarvis conjecture is true for ℓ-controllable Latin group codes because every Latin square $\Box_0$ constructed by the automorphism method is isotopic to a group table (it is a rearrangement of the columns of a group table). Using the above approach, we can show the Sarvis conjecture is true for an ℓ-controllable homogeneous Latin trellis as well.

For a group code used to convey binary information, a *bit-oriented group code*, $|X_0|$ must be some power of 2 because the input information stream is binary.

Theorem 23 *In an* ℓ*-controllable bit-oriented Latin group code,* X_0 *is an abelian* p*-group and* G *is a* p*-group,* $p = 2$*.*

Proof From Theorem 12, we have

$$\frac{|X_{j+1}|}{|X_j|} = \frac{|X_0|}{|\Delta_j|}.$$

But $|X_0|$ is a power of 2 and so any subgroup Δ_j of X_0 must have order a power of 2. Thus $|X_0|/|\Delta_j|$ is a power of 2, and so

$$|G| = |X_0| \prod_{j=1}^{\ell-1} \frac{|X_{j+1}|}{|X_j|}$$

must be a power of 2. •

Trott and Sarvis have observed that $\square_0$ of all published homogeneous trellis codes is the group table of $\mathbf{Z}^2 \times \mathbf{Z}^2 \times \cdots \times \mathbf{Z}^2$ [8]. The theorem above indicates that practical (bit-oriented) Latin group codes might be constructed for which this is not true, but that indeed $\square_0$ is based on an abelian 2-group.

We say shift group G is a *Latin shift group* if it has a shift structure $(\{X_j\}, Y_0, \varphi)$ with $X_0 \cap Y_0 = \mathbf{1}$, $X_0 \simeq Y_0$, and X_0, Y_0 abelian.

The previous results show some similarities of the mathematical structure of a Latin square and Latin shift group. We now show a more direct analogy. Recall that we have shown the following relations for Latin square $\square_0$.

Proposition 24 *The $(t,3)$ net $\square_0$ has translation group $K_0 = X_0 Y_0$ which is a $(t,3)$ PCP with the following properties:*
(1) X_0, Y_0, and K_{a} are disjoint.
(2) $K_0 = X_0 Y_0 = X_0 K_{\mathsf{a}} = Y_0 K_{\mathsf{a}}$.
(3) $X_0 \lhd K_0$, $Y_0 \lhd K_0$, $K_{\mathsf{a}} \lhd K_0$.
(4) $K_0 \simeq X_0 \times Y_0$, $K_0 \simeq X_0 \times K_{\mathsf{a}}$, $K_0 \simeq Y_0 \times K_{\mathsf{a}}$.
(5) $X_0 \simeq Y_0 \simeq K_{\mathsf{a}}$.

We now show that similar properties hold for Latin clique C_0. A *partial net* is a generalization of a net in which lines from different classes need not intersect [23]. Latin clique C_0 is a partial net with three parallel classes of lines. The first (second) parallel class of lines are the rows (columns) of Latin squares that comprise C_0. Thus lines in the first parallel class are the rows $\{gX_0 | g \in G_0\}$, and lines in the second parallel class are the columns $\{gY_0 | g \in G_0\}$. Note that a row and column do not intersect unless they are from the same square, in which case they intersect once. The third parallel class consists of lines formed by entries in all squares having the same label. For example, line L_{a} consists of all entries with label a; of course $l_{\mathsf{a}} \subset L_{\mathsf{a}}$. Note that a line in the third parallel class intersects each row and each column exactly once. Since G_{a} is the stabilizer of L_{a}, this means $G_{\mathsf{a}} \cap X_0 = G_{\mathsf{a}} \cap Y_0 = \mathbf{1}$. Note that each row and column has $|X_0| = |Y_0|$ points, and each line in the third parallel class has $|G_0|/|X_0|$ points. Then $|G_0| = |G_{\mathsf{a}}||X_0|$, giving $G_0 \simeq X_0 \times G_{\mathsf{a}}$. This gives the following result.

Proposition 25 *The partial net C_0 has translation group G_0 with the following properties:*
(1) X_0, Y_0, and G_{a} are disjoint.
(2) $G_0 = X_0 G_{\mathsf{a}} = Y_0 G_{\mathsf{a}}$.
(3) $X_0 \lhd G_0$, $Y_0 \lhd G_0$, $G_{\mathsf{a}} \lhd G_0$.
(4) $G_0 \simeq X_0 \times G_{\mathsf{a}}$, $G_0 \simeq Y_0 \times G_{\mathsf{a}}$.
Note we also have $G_0/(X_0 Y_0) \simeq G_{\mathsf{a}}/K_{\mathsf{a}}$.

Comparing Proposition 24 and Proposition 25, we see that (1)-(4) of Proposition 25 correspond to (1)-(4) of Proposition 24. Thus we see the mathematical structure of Latin clique C_0 is analogous to the mathematical structure of Latin square $\square_0$. Also note that from (4) of Proposition 25, we can obtain $G_0/X_0 \simeq G_{\mathsf{a}}$ and $G_0/Y_0 \simeq G_{\mathsf{a}}$, or just $G_0/X_0 \simeq G_0/Y_0$, which is the isomorphism constructed by Sarvis and Trott in their algorithm [10].

The shift group G is itself the translation group of a partial net with three parallel classes of lines. The first (second) parallel class of lines are the rows (columns) of Latin squares that comprise $\mathcal{G}_G$. Thus lines in the first parallel class are the rows $\{gX_0 | g \in G\}$, and lines in the second parallel class are the columns $\{gY_0 | g \in G\}$. The third parallel class consists of lines in each square formed by entries having the same label; line l_{a} is an example. Note that lines in different classes intersect exactly once if they are from the same square, and otherwise do not intersect. This means that any collection of lines in the third parallel class, with exactly one line from each square, forms a right transveral of G/X_0 and G/Y_0.

Theorem 26 *In a Latin shift group G, there is a set G_v of G which is a right transveral of G/X_0 and G/Y_0, where $G_v \supset G_{\mathsf{a}} \supset K_{\mathsf{a}}$.*

Proposition 27 *The graph $\mathcal{G}_G$ of an ℓ-controllable Latin group code $(\mathcal{G}_G, \omega)$ has translation group G with the following properties:*
(1) X_0, Y_0, and G_v are disjoint.
(2) $G = X_0 G_v = Y_0 G_v$.
(3) $X_0 \lhd G$, $Y_0 \lhd G$, $K_{\mathsf{a}} \subset G_{\mathsf{a}} \subset G_v \subset G$.
(4) G_v is a right transversal of G/X_0 and G/Y_0.
Note we also have $K_{\mathsf{a}} \lhd G$ and $G_{\mathsf{a}} \lhd G$.

We see that (1)-(4) of Proposition 27 correspond to (1)-(4) of Proposition 25. Taken together, Propositions 24, 25, and 27 show that the Latin group code has a mathematical structure similar to the Latin square. In this sense, we can say that the Latin group code is a natural generalization of a Latin square to a sequence space.

As previously mentioned, when X_0 is elementary abelian, a complete set of $|X_0| - 1$ mutually orthogonal Latin squares based on X_0 can be constructed. In this case then, we can construct a *mutually orthogonal Latin group code* in which Latin square $\square_0$ is replaced by $|X_0|-1$ mutually orthogonal Latin squares, a translation plane.

4 The subdirect product group and state group

In this section, we assume group G has a shift structure $(\{X_j\}, Y_0, \varphi)$. Then G has a normal chain $\{X_j\}$ with $X_\ell = G$ and each $X_j \lhd G$, a normal subgroup Y_0, and an isomorphism φ from G/Y_0 onto G/X_0 such that

$$\varphi(X_j Y_0 / Y_0) = X_{j+1}/X_0 \tag{59}$$

for $-1 \leq j < \ell$. Define

$$G_X \stackrel{\text{def}}{=} G/Y_0$$

and

$$G_Y \stackrel{\text{def}}{=} G/X_0.$$

Defined in this manner, G_X increments along the horizontal axis in Figure 3, and G_Y increments along the vertical axis. Groups G_X and G_Y are called *state groups* of shift group G. Define

$$G_X^j \overset{\text{def}}{=} \frac{X_j Y_0}{Y_0}$$

for $-1 \leq j \leq \ell$, and

$$G_Y^j \overset{\text{def}}{=} X_j/X_0,$$

for $0 \leq j \leq \ell$. We see that $G_X^{-1} = Y_0/Y_0 = \mathbf{1}$, $G_Y^0 = X_0/X_0 = \mathbf{1}$, $G_X^{\ell-1} = G_X^{\ell} = G_X$, and $G_Y^{\ell} = G_Y$. Note that $G_X^j \lhd G_X$ for $-1 \leq j \leq \ell$, and $G_Y^j \lhd G_Y$ for $0 \leq j \leq \ell$. With these definitions, we can rewrite (59) as

$$\varphi(G_X^j) = G_Y^{j+1} \tag{60}$$

for $-1 \leq j < \ell$; we can rewrite the isomorphism $\varphi : G/Y_0 \to G/X_0$ as $\varphi : G_X \to G_Y$ or $\varphi(G_X) = G_Y$.

We can think of graph $\mathcal{G}_G$ as essentially a bipartite graph $\mathcal{G}_\ell$ with input states G_Y and output states G_X. An element $g \in X_\ell$ splits from input state gX_0 and merges to output state gY_0. In addition, there is an isomorphism $\varphi : G_X \to G_Y$ from output states to input states. In graph $\mathcal{G}_\ell$ all the output states are connected to input states via the isomorphism $\varphi(G_X) = G_Y$.

In the same manner, we can associate a bipartite graph $\mathcal{G}_j$ with X_j, for $0 \leq j < \ell$. An element $g \in X_j$ splits from input state gX_0 and merges to output state gY_0. Then it is clear that the input states of $\mathcal{G}_j$ are cosets in $G_Y^j = X_j/X_0$ and the output states are cosets in $G_X^j = X_jY_0/Y_0$. There are $|X_0|$ edges which split from each input state, and $|X_j \cap Y_0|$ edges which merge to each output state. Since $|X_j \cap Y_0| < |X_0|$ for $j < \ell$, there are more output states than input states. Some of the output states are connected to input states via the isomorphism $\varphi(G_X^{j-1}) = G_Y^j$, but some of the output states are not connected to input states. In this sense the graph $\mathcal{G}^j$ is not "controllable" for $0 \leq j < \ell$. The graph $\mathcal{G}_{-1}$ is the trivial bipartite graph with one edge from input state X_0 to output state Y_0.

The input states of $\mathcal{G}_{j+1}$ are G_Y^{j+1}, and the output states are G_X^{j+1}. Then it is clear by construction that $\mathcal{G}_j$ is a subgraph of $\mathcal{G}_{j+1}$, for $-1 \leq j < \ell$ (the input states of $\mathcal{G}_\ell$ are $G_Y^\ell = G_Y$ and the output states are $G_X^\ell = G_X$). Thus we have exhibited a sequence of graphs $\mathcal{G}_j$ that converges to $\mathcal{G}_\ell$, where $\mathcal{G}_j$ is a subgraph of $\mathcal{G}_{j+1}$ and $\mathcal{G}_\ell$ is essentially $\mathcal{G}_G$. This observation forms the basis of the algorithm in Section 5.

Note that $X_j \cap Y_0$ plays the same role in X_j as Y_0 plays in G. By the second isomorphism theorem, we have

$$\frac{X_j Y_0}{Y_0} \simeq \frac{X_j}{X_j \cap Y_0}$$

and there is a 1-1 correspondence between cosets of Y_0 in X_jY_0/Y_0 and cosets of $X_j \cap Y_0$ in $X_j/X_j \cap Y_0$ (this isomorphism and correspondence can be clearly seen using Figure 3). Thus we have

$$\frac{X_j(X_j \cap Y_0)}{X_j \cap Y_0} = \frac{X_j}{X_j \cap Y_0} \simeq \frac{X_j Y_0}{Y_0} = G_X^j. \tag{61}$$

Using (61) and $G_Y^j = X_j/X_0$, we can define a graph isomorphic to $\mathcal{G}_j$ which only uses elements in X_j.

We further restrict the shift groups G that we consider to those with $X_0 \cap Y_0 = \mathbf{1}$. We say such a shift group is *reduced.* The following proposition shows that there is essentially no loss in generality in doing so.

Proposition 28 *Any shift group G with $|X_0 \cap Y_0| > 1$ is an extension of $X_0 \cap Y_0$ by a shift group $\dot{G}$, where $\dot{G}$ has $\dot{X}_0 \cap \dot{Y}_0 = \mathbf{1}$.*

Each element $g \in G$ is in one and only one coset of Y_0 and one and only one coset of X_0. Let $\gamma : G \to G_X \times G_Y$ represent this correspondence using the assignment $g \mapsto (g_x, g_y)$; note that γ is well defined. The map γ is a homomorphism from G into $G_X \times G_Y$: if $\gamma(g) = (g_x, g_y)$ and $\gamma(g') = (g'_x, g'_y)$, then gg' must be in coset $g_xg'_x$ of Y_0 and coset $g_yg'_y$ of X_0, or $\gamma(gg') = (g_xg'_x, g_yg'_y)$. Let $\tilde{G} = \gamma(G)$. Then $\tilde{G}$ is a subgroup of $G_X \times G_Y$. Since $|X_0 \cap Y_0| = 1$, from Proposition 17 a coset of X_0 and a coset of Y_0 intersect in at most one element of G. Thus the map $\gamma : G \to \tilde{G}$ is a bijection, and in fact γ is an isomorphism. Let $G \overset{\gamma}{\simeq} \tilde{G}$ denote the isomorphism given by the correspondence γ.

Let $\gamma_x : G \to G_X$ be the projection of γ onto its first coordinate, i.e., $\gamma_x : g \mapsto g_x$. Similarly, let $\gamma_y : G \to G_Y$ be the projection of γ onto its second coordinate, i.e., $\gamma_y : g \mapsto g_y$. We know that $\tilde{G}$ is a subgroup of the direct product $G_X \times G_Y$. Moreover, since $\gamma_x : G \to G_X$ is onto, and $\gamma_y : G \to G_Y$ is onto, we have that $\tilde{G}$ is a subdirect product of G_X and G_Y. (As in [15], we say H is a *subdirect product* of H_X and H_Y if it is a subgroup of $H_X \times H_Y$ and the first and second coordinate of H take all values in H_X and H_Y, respectively; we also say H is a subdirect product of $H_X \times H_Y$.)

Define $\tilde{X}_j \subset \tilde{G}$ by $\tilde{X}_j \overset{\text{def}}{=} \gamma(X_j)$, for $-1 \leq j \leq \ell$. Consider the subgroup X_j of G for $0 \leq j \leq \ell$. We now determine the image $\gamma_x(X_j)$. But $\gamma_x(X_j)$ must be the cosets of Y_0 in $G_X = G/Y_0$ that intersect X_j; these must be the elements in subgroup X_jY_0/Y_0. Thus we must have $\gamma_x(X_j) = X_jY_0/Y_0$ and $\gamma_x(X_j)$ is onto X_jY_0/Y_0. The image $\gamma_y(X_j)$ is just the cosets of X_0 in $G_Y = G/X_0$ that intersect X_j. Thus $\gamma_y(X_j) = X_j/X_0$ and $\gamma_y(X_j)$ is onto X_j/X_0. Thus we have shown $\tilde{X}_j$ is a subdirect product of X_jY_0/Y_0 and X_j/X_0.

It is easy to see that $\tilde{X}_{-1}$ is a subdirect product of Y_0/Y_0 and X_0/X_0, and in fact $\tilde{X}_{-1} = \mathbf{1} \times \mathbf{1}$.

Proposition 29 *$\tilde{G}$ is a subdirect product of $G_X \times G_Y$. $\tilde{X}_j$ is a subdirect product of $G_X^j \times G_Y^j$, for $0 \leq j \leq \ell$. $\tilde{X}_{-1}$ is a subdirect product of $G_X^{-1} \times G_Y^0$, and $\tilde{X}_{-1} = \mathbf{1} \times \mathbf{1}$.*

As with X_j, we can associate a graph $\tilde{\mathcal{G}}_j$ with $\tilde{X}_j$. In $\tilde{\mathcal{G}}_j$, if $\tilde{g} = (g_x, g_y) \in \tilde{X}_j$, then $\tilde{g}$ is an edge from input state g_y to output state g_x. Since $\tilde{X}_j$ is a subdirect product of $G_X^j \times G_Y^j$, the input states of $\tilde{\mathcal{G}}_j$ are G_Y^j and the output states are G_X^j. Let $\tilde{g} = \gamma(g)$. In graph $\mathcal{G}_j$, g is an edge from input state gX_0 to output state gY_0. But we must have $\gamma_y(g) = gX_0 = g_y$ and $\gamma_x(g) = gY_0 = g_x$. Thus $\tilde{g}$ is an edge in $\tilde{\mathcal{G}}_j$ with input state g_y and output state g_x if and only if $g = \gamma^{-1}(\tilde{g})$ is an edge in $\mathcal{G}_j$ with input state g_y and output state g_x. Thus $\tilde{\mathcal{G}}_j$ is isomorphic to $\mathcal{G}_j$. For $\tilde{\mathcal{G}}_j$, there is an isomorphism $\varphi : G_X^{j-1} \to G_Y^j$ from some of the output states to input states, the same as for $\mathcal{G}_j$. As for X_j, it can be shown that $\tilde{\mathcal{G}}_j$ is a subgraph of $\tilde{\mathcal{G}}_{j+1}$. Thus we have found a sequence of graphs $\tilde{\mathcal{G}}_j$ that converges to $\tilde{\mathcal{G}}_\ell$ where $\tilde{\mathcal{G}}_j$ is a subgraph of $\tilde{\mathcal{G}}_{j+1}$ and $\tilde{\mathcal{G}}_\ell$ is essentially $\mathcal{G}_G$.

We now examine the image of X_0 under γ. We know $\tilde{X}_0 = \gamma(X_0)$. We have $\gamma_x(X_0) = X_0Y_0/Y_0 \simeq X_0$ (since X_0Y_0 has $X_0 \lhd X_0Y_0$, $Y_0 \lhd X_0Y_0$, and $X_0 \cap Y_0 = \mathbf{1}$, define the homomorphism $\kappa : xy \mapsto x$; then the kernel is Y_0 and the first isomorphism theorem gives the result) and $\gamma_y(X_0) = X_0/X_0 = \mathbf{1}$. Define $X_0' \stackrel{\text{def}}{=} X_0Y_0/Y_0$. Then $\tilde{X}_0$ is a subdirect product of $X_0' \times \mathbf{1}$. But in this case we have $\tilde{X}_0 = X_0' \times \mathbf{1}$.

Now examine the image of Y_0 under γ. Define $\tilde{Y}_0 \stackrel{\text{def}}{=} \gamma(Y_0)$. We have $\gamma_x(Y_0) = Y_0/Y_0 = \mathbf{1}$ and $\gamma_y(Y_0) = X_0Y_0/X_0 \simeq Y_0$. Define $Y_0'' \stackrel{\text{def}}{=} X_0Y_0/X_0$. Then $\tilde{Y}_0$ is a subdirect product of $\mathbf{1} \times Y_0''$, and in this case $\tilde{Y}_0 = \mathbf{1} \times Y_0''$.

These results give

$$\begin{aligned} \gamma(X_0Y_0) &= \tilde{X}_0\tilde{Y}_0 && (62)\\ &= (X_0' \times \mathbf{1})(\mathbf{1} \times Y_0'') && (63)\\ &= X_0' \times Y_0''. && (64) \end{aligned}$$

Note that we will use a prime for subgroups of the G_X coordinate and a double prime for subgroups of the G_Y coordinate.

Theorem 30 *$\tilde{G}$ is a subdirect product of $G_X \times G_Y$. $\tilde{G}$ contains a normal subgroup $\tilde{X}_0\tilde{Y}_0 = X_0' \times Y_0''$ such that*

$$X_0' \times Y_0'' \simeq X_0 \times Y_0,$$

where $\tilde{X}_0 = X_0' \times \mathbf{1}$ and $\tilde{Y}_0 = \mathbf{1} \times Y_0''$. Then $G_X = G/Y_0$ contains a group $X_0' \simeq X_0$ and $X_0' \lhd G_X$. Further $G_Y = G/X_0$ contains a group $Y_0'' \simeq Y_0$ and $Y_0'' \lhd G_Y$. $\tilde{X}_0$ are all the elements of $\tilde{G}$ with second coordinate equal $\mathbf{1}$. $\tilde{Y}_0$ are all the elements of $\tilde{G}$ with first coordinate equal $\mathbf{1}$.

Proof Since $G_Y = G/X_0$, the only elements of G for which $G_Y = \mathbf{1}$ are subgroup X_0. Thus the only elements of $\tilde{G}$ with second coordinate $\mathbf{1}$ are $\tilde{X}_0$. Similarly, since $G_X = G/Y_0$, the only elements of G for which $G_X = \mathbf{1}$ are Y_0. •

Theorem 31 *$\tilde{G}$ is a subdirect product of groups G_X and G_Y if and only if there is an isomorphism*

$$\frac{G_X}{X_0'} \simeq K \simeq \frac{G_Y}{Y_0''} \qquad (65)$$

such that (g_x, g_y), where $g_x \in G_X$ and $g_y \in G_Y$, is an element of $\tilde{G}$ if and only if g_x and g_y have the same image $k \in K$ in the homomorphisms $G_X \to K$, $G_Y \to K$.

Proof The only elements of $\tilde{G}$ that have the identity $\mathbf{1}$ in the second coordinate are $\tilde{X}_0 = X_0' \times \mathbf{1}$. The only elements of $\tilde{G}$ that have the identity $\mathbf{1}$ in the first coordinate are $\tilde{Y}_0 = \mathbf{1} \times Y_0''$. Then the theorem is just an application of the subdirect product theorem in Hall's text [15]. •

In general, when the condition in Theorem 31 holds, we say $\tilde{G}$ is a subdirect product of $G_X \times G_Y$ *implied by* the isomorphism (65).

Fix j, $0 \le j \le \ell$. Define $\Lambda_j \stackrel{\text{def}}{=} X_j \cap Y_0$. We now examine the image of Λ_j under γ. Define $\tilde{\Lambda}_j \stackrel{\text{def}}{=} \gamma(\Lambda_j)$. The image $\gamma_x(X_j \cap Y_0)$ is the cosets of Y_0 in $G_X = G/Y_0$ that intersect $X_j \cap Y_0$. Then $\gamma_x(X_j \cap Y_0) = Y_0/Y_0 = \mathbf{1}$. And $\gamma_y(X_j \cap Y_0)$ is the cosets of X_0 in $G_Y = G/X_0$ that intersect $X_j \cap Y_0$. Then

$$\gamma_y(X_j \cap Y_0) = \frac{X_j}{X_0} \cap \frac{X_0Y_0}{Y_0}.$$

Define

$$\Lambda_j'' \stackrel{\text{def}}{=} \frac{X_j}{X_0} \cap \frac{X_0Y_0}{Y_0}.$$

Thus $\tilde{\Lambda}_j$ is a subdirect product of $\mathbf{1} \times \Lambda_j''$, and so in fact $\tilde{\Lambda}_j = \mathbf{1} \times \Lambda_j''$. Note that $\Lambda_j'' = G_Y^j \cap Y_0''$ and $\Lambda_j'' \lhd G_Y$. Also $\Lambda_0'' = X_0/X_0 = \mathbf{1}$ and $\tilde{\Lambda}_j \lhd \tilde{G}$.

Theorem 32 *Fix j, $0 \le j \le \ell$. $\tilde{X}_j$ is a subdirect product of $G_X^j \times G_Y^j$. $\tilde{X}_j$ contains a normal subgroup $\tilde{X}_0\tilde{\Lambda}_j = X_0' \times \Lambda_j''$ such that*

$$X_0' \times \Lambda_j'' \simeq X_0 \times \Lambda_j,$$

where $\tilde{X}_0 = X_0' \times \mathbf{1}$ and $\tilde{\Lambda}_j = \mathbf{1} \times \Lambda_j''$. Then $G_X^j = X_jY_0/Y_0$ contains a group $X_0' \simeq X_0$ and $X_0' \lhd G_X$. Further $G_Y^j = X_j/X_0$ contains a group Λ_j'' such that $\Lambda_j'' \simeq \Lambda_j$, $\Lambda_j'' = G_Y^j \cap Y_0''$, and $\Lambda_j'' \lhd G_Y$. $\tilde{X}_0$ are all the elements of $\tilde{X}_j$ with second coordinate equal $\mathbf{1}$. $\tilde{\Lambda}_j$ are all the elements of $\tilde{X}_j$ with first coordinate equal $\mathbf{1}$.

Proof Since $\gamma_x(X_j)$ is the cosets of Y_0 in $G_X = G/Y_0$ that intersect X_j, the only elements g of X_j for which $\gamma_x(g) = Y_0/Y_0 = \mathbf{1}$ are $g \in X_j \cap Y_0$. Thus the only elements of $\tilde{X}_j$ that have the identity $\mathbf{1}$ in the first coordinate are $\gamma(X_j \cap Y_0) = \tilde{\Lambda}_j$. •

We can now give a necessary and sufficient condition that guarantees $\tilde{X}_j$ is a subdirect product of groups G_X^j and G_Y^j.

Theorem 33 *For $0 \le j \le \ell$, $\tilde{X}_j$ is a subdirect product of groups G_X^j and G_Y^j if and only if there is an isomorphism*

$$\frac{G_X^j}{X_0'} \simeq K \simeq \frac{G_Y^j}{\Lambda_j''} \qquad (66)$$

such that (g_x, g_y)*, where* $g_x \in G_X^j$ *and* $g_y \in G_Y^j$*, is an element of* $\tilde{X}_j$ *if and only if* g_x *and* g_y *have the same image* $k \in K$ *in the homomorphisms* $G_X^j \to K$*,* $G_Y^j \to K$*.*

Proof The only elements of $\tilde{X}_j$ that have the identity $\mathbf{1}$ in the second coordinate are $\tilde{X}_0 = X_0' \times \mathbf{1}$. The only elements of $\tilde{X}_j$ that have the identity $\mathbf{1}$ in the first coordinate are $\tilde{\Lambda}_j = \mathbf{1} \times \Lambda_j''$. Then the theorem is just an application of the subdirect product theorem in Hall's text [15]. •

From Lemma 7, we have $X_j^* = X_j(X_{j+1} \cap Y_0) = X_j\Lambda_{j+1}$, for $-1 \le j < \ell$. Define $\tilde{X}_j^* \overset{\text{def}}{=} \gamma(X_j^*)$. Then under the isomorphism $G \overset{\gamma}{\simeq} \tilde{G}$,

$$\begin{aligned} \tilde{X}_j^* &= \tilde{X}_j \tilde{\Lambda}_{j+1} \\ &= \tilde{X}_j(\mathbf{1} \times \Lambda''_{j+1}). \end{aligned} \tag{67}$$

Define $G_Y^{j*} \overset{\text{def}}{=} G_Y^j \Lambda''_{j+1}$. Since $G_Y^j \lhd G_Y^{j+1}$ and $\Lambda''_{j+1} \lhd G_Y^{j+1}$, then G_Y^{j*} is a subgroup of G_Y^{j+1} and

$$G_Y^j \lhd G_Y^{j*} \lhd G_Y^{j+1}.$$

Then $\tilde{X}_j^*$ is a subdirect product of $G_X^j \times G_Y^{j*}$.

For $j = \ell - 1$ we know

$$X_{\ell-1}^* = X_{\ell-1} Y_0 = X_\ell.$$

Then under the isomorphism $G \overset{\gamma}{\simeq} \tilde{G}$,

$$\begin{aligned} \tilde{X}_{\ell-1}^* &= \tilde{X}_{\ell-1}(\mathbf{1} \times \Lambda_\ell'') \\ &= \tilde{X}_{\ell-1}(\mathbf{1} \times Y_0''). \end{aligned}$$

Since $\tilde{X}_{\ell-1}^* = \tilde{X}_\ell$, and $\tilde{X}_\ell$ is a subdirect product of $G_X^\ell \times G_Y^\ell$, this means

$$G_X^{\ell-1} = G_X^\ell = G_X,$$

and

$$G_Y^{\ell-1} Y_0'' = G_Y^{\ell-1*} = G_Y^\ell = G_Y.$$

The isomorphism $\gamma : G \overset{\gamma}{\simeq} \tilde{G}$ induces isomorphisms

$$G_X = G/Y_0 \simeq \tilde{G}/\tilde{Y}_0, \tag{68}$$

$$G_Y = G/X_0 \simeq \tilde{G}/\tilde{X}_0, \tag{69}$$

$$G_X^j = X_j Y_0 / Y_0 \simeq \tilde{X}_j \tilde{Y}_0 / \tilde{Y}_0, \tag{70}$$

$$G_Y^j = X_j / X_0 \simeq \tilde{X}_j / \tilde{X}_0. \tag{71}$$

Proposition 34 *If a group* G *has a shift structure* $(\{X_j\}, Y_0, \varphi)$ *and* $|X_0 \cap Y_0| = 1$*, then under the isomorphism* $G \overset{\gamma}{\simeq} \tilde{G}$*, the group* $\tilde{G}$ *is a subdirect product of* G_X *and* G_Y*. Further group* $\tilde{G}$ *has a shift structure* $(\{\tilde{X}_j\}, \tilde{Y}_0, \tilde{\varphi})$*, where we have* $\tilde{X}_j = \gamma(X_j)$*,* $\tilde{Y}_0 = \gamma(Y_0)$*, and the isomorphism* $\tilde{\varphi} : \tilde{G}/\tilde{Y}_0 \to \tilde{G}/\tilde{X}_0$ *is just the isomorphism* $\varphi : G/Y_0 \to G/X_0$*.*

Proof By the preceding results, we have shown there is an isomorphism $G \overset{\gamma}{\simeq} \tilde{G}$, where $\tilde{G}$ is a subdirect product of G_X and G_Y. From the correspondence theorem, under the isomorphism γ, the normal chain $\{X_j\}$ gives a normal chain $\{\tilde{X}_j\}$ with $\tilde{X}_\ell = \tilde{G}$ and each $\tilde{X}_j \lhd \tilde{G}$, and the normal subgroup Y_0 gives a normal subgroup $\tilde{Y}_0$. Under the isomorphism γ, the isomorphism $\varphi : G/Y_0 \to G/X_0$ induces an isomorphism $\tilde{\varphi} : \tilde{G}/\tilde{Y}_0 \to \tilde{G}/\tilde{X}_0$ and $\tilde{\varphi}(\tilde{X}_j \tilde{Y}_0 / \tilde{Y}_0) = \tilde{X}_{j+1}/\tilde{X}_0$. •

We can summarize some of the results in this section as follows.

Theorem 35 *Let* G *be a group with a shift structure* $(\{X_j\}, Y_0, \varphi)$ *and* $|X_0 \cap Y_0| = 1$*. Define* $G_X^j \overset{\text{def}}{=} X_j Y_0 / Y_0$ *and* $G_Y^j \overset{\text{def}}{=} X_j / X_0$*. There is a normal chain*

$$\begin{aligned} \mathbf{1} = G_X^{-1} \lhd X_0' = G_X^0 \lhd G_X^1 \lhd \cdots \lhd G_X^j \lhd \cdots \\ \lhd G_X^{\ell-1} = G_X^\ell = G_X, \end{aligned}$$

where each $G_X^j \lhd G_X$*,* $0 \le j \le \ell$*. There are normal chains*

$$\begin{aligned} \mathbf{1} = G_Y^0 \lhd G_Y^{0*} \lhd G_Y^1 \lhd G_Y^{1*} \lhd \cdots \lhd G_Y^j \lhd G_Y^{j*} \lhd \\ \cdots \lhd G_Y^{\ell-1} \lhd G_Y^{\ell-1*} = G_Y^\ell = G_Y, \end{aligned}$$

and

$$\mathbf{1} = \Lambda_0'' \lhd \Lambda_1'' \lhd \cdots \lhd \Lambda_j'' \lhd \cdots \lhd \Lambda_\ell'' = Y_0'',$$

where each $G_Y^j \lhd G_Y$*,* $G_Y^{j*} \lhd G_Y$*, and each* $\Lambda_j'' \lhd G_Y$ *and* $Y_0'' \lhd G_Y$*, such that* $G_Y^j \cap Y_0'' = \Lambda_j''$ *and* $G_Y^{j*} = G_Y^j \Lambda_{j+1}''$*. There is an isomorphism* $\varphi : G_X \to G_Y$ *such that* $\varphi : G_X^j \mapsto G_Y^{j+1}$ *for* $-1 \le j < \ell$*.*

Under the isomorphism $G \overset{\gamma}{\simeq} \tilde{G}$*, the group* $\tilde{G}$ *is a subdirect product of* G_X *and* G_Y*. Further group* $\tilde{G}$ *has a shift structure* $(\{\tilde{X}_j\}, \tilde{Y}_0, \tilde{\varphi})$*, where we have* $\tilde{X}_j = \gamma(X_j)$*,* $\tilde{Y}_0 = \gamma(Y_0)$*, and isomorphism* $\tilde{\varphi}$ *is closely related to* φ*. We have* $\tilde{X}_{-1} = \mathbf{1} \times \mathbf{1}$*,* $\tilde{X}_0 = X_0' \times \mathbf{1}$*, and* $\tilde{Y}_0 = \mathbf{1} \times Y_0''$*. For* $0 \le j \le \ell$*,* $X_0' \times \mathbf{1}$ *are the only elements of* $\tilde{X}_j$ *with* $\mathbf{1}$ *in the second coordinate, and* $\mathbf{1} \times \Lambda_j''$ *are the only elements of* $\tilde{X}_j$ *with* $\mathbf{1}$ *in the first coordinate. Lastly, for* $0 \le j \le \ell$*,* $\tilde{X}_j$ *is a subdirect product of* G_X^j *and* G_Y^j*, and there is an isomorphism*

$$\frac{G_X^j}{X_0'} \simeq K \simeq \frac{G_Y^j}{\Lambda_j''} \tag{72}$$

such that $(g_x, g_y) \in \tilde{X}_j$ *if and only if* g_x *and* g_y *have the same image* $k \in K$ *in the homomorphisms* $G_X^j \to K$*,* $G_Y^j \to K$*.*

Since G has a shift structure $(\{X_j\}, Y_0, \varphi)$, we know that $X_j \subset X_{j+1}$. Under the isomorphism $G \overset{\gamma}{\simeq} \tilde{G}$, we have $\tilde{X}_j \subset \tilde{X}_{j+1}$ for the subdirect product group $\tilde{G}$. We now give a necessary and sufficient condition for $\tilde{X}_j \subset \tilde{X}_{j+1}$ to hold.

Lemma 36 *Fix arbitrary integer* j, $j \geq 0$. *Assume there are three (trivial) normal chains*

$$H_U^j \lhd H_U^{j+1}, \tag{73}$$

$$H_V^j \lhd H_V^{j+1}, \tag{74}$$

$$\Gamma''_j \lhd \Gamma''_{j+1}, \tag{75}$$

where $U'_0 \lhd H_U^{j+1}$, $\Gamma''_j \lhd H_V^j$, $\Gamma''_{j+1} \lhd H_V^{j+1}$, *and* $H_V^j \cap \Gamma''_{j+1} = \Gamma''_j$. *Since* $H_V^j \lhd H_V^{j+1}$ *and* $\Gamma''_{j+1} \lhd H_V^{j+1}$, *there is a subgroup* $H_V^{j*} = H_V^j \Gamma''_{j+1}$ *of* H_V^{j+1} *such that*

$$H_V^j \lhd H_V^{j*} \lhd H_V^{j+1}.$$

Assume the three normal chains (73)-(75) are related such that there are isomorphisms

$$\beta_j : \frac{H_U^j}{U'_0} \to \frac{H_V^j}{\Gamma''_j}$$

and

$$\beta_{j+1} : \frac{H_U^{j+1}}{U'_0} \to \frac{H_V^{j+1}}{\Gamma''_{j+1}}.$$

Let $\tilde{U}_j$ *be the subdirect product of* $H_U^j \times H_V^j$ *implied by the isomorphism* β_j, *and let* $\tilde{U}_{j+1}$ *be the subdirect product of* $H_U^{j+1} \times H_V^{j+1}$ *implied by the isomorphism* β_{j+1}. *Let* η''_j *be the isomorphism*

$$\eta''_j : H_V^j/\Gamma''_j \to H_V^{j*}/\Gamma''_{j+1}$$

with assignment $h_v\Gamma''_j \mapsto h_v\Gamma''_{j+1}$ *for* $h_v \in H_V^j$, *given by (2) of Lemma 6 using* $H_V^j\Gamma''_{j+1} = H_V^{j*}$ *in the hypothesis. Then the composition* $\eta''_j \circ \beta_j$ *is an isomorphism* β_j^*,

$$\beta_j^* : H_U^j/U'_0 \to H_V^{j*}/\Gamma''_{j+1}$$

(see Figure 4). We have $\tilde{U}_j \subset \tilde{U}_{j+1}$ *if and only if the restriction of the isomorphism* β_{j+1} *to* H_U^j/U'_0 *is isomorphism* β_j^*. *In this case there is a group* $\tilde{U}_j^*$ *such that* $\tilde{U}_j \subset \tilde{U}_j^* \subset \tilde{U}_{j+1}$ *where* $\tilde{U}_j^*$ *is a subdirect product of* $H_U^j \times H_V^{j*}$ *implied by the isomorphism* β_j^*.

$$\begin{tikzcd}
H_U^j/U'_0 \arrow[r, "\beta_j"] \arrow[dr, "\beta_j^*"'] & H_V^j/\Gamma''_j \arrow[d, "\eta''_j"] \\
& H_V^{j*}/\Gamma''_{j+1}
\end{tikzcd}$$

Figure 4: Commutative diagram.

Proof Since H_V^j and Γ''_{j+1} are normal subgroups of H_V^{j+1}, we have $H_V^{j*} = H_V^j\Gamma''_{j+1}$ is a normal subgroup of H_V^{j+1}.

Refer to Figure 4. Fix $cU'_0 \in H_U^j/U'_0$, where $c \in H_U^j$. Let the isomorphism β_j make the assignment

$$\beta_j : cU'_0 \mapsto d\Gamma''_j,$$

where $d \in H_V^j$. The isomorphism $\eta''_j : H_V^j/\Gamma''_j \to H_V^{j*}/\Gamma''_{j+1}$ gives the assignment

$$d\Gamma''_j \mapsto d\Gamma''_{j+1}.$$

Then the isomorphism β_j^* makes the assignment

$$\beta_j^* : cU'_0 \mapsto d\Gamma''_{j+1}. \tag{76}$$

First assume $\tilde{U}_j \subset \tilde{U}_{j+1}$. We show the restriction of β_{j+1} to H_U^j/U'_0 is β_j^*. Since β_j makes the assignment $\beta_j : cU'_0 \mapsto d\Gamma''_j$, the elements $cU'_0 \times d\Gamma''_j$ are in $\tilde{U}_j$. Since $\tilde{U}_j \subset \tilde{U}_{j+1}$, then $cU'_0 \times d\Gamma''_j \subset \tilde{U}_{j+1}$. But since $\Gamma''_j \subset \Gamma''_{j+1} \subset H_V^{j+1}$ by assumption, then $cU'_0 \times d\Gamma''_{j+1} \subset \tilde{U}_{j+1}$. Then the isomorphism β_{j+1} makes the assignment

$$\beta_{j+1} : cU'_0 \mapsto d\Gamma''_{j+1}. \tag{77}$$

Comparing (76) and (77) shows that the restriction of β_{j+1} to H_U^j/U'_0 is β_j^*.

Now assume the restriction of β_{j+1} to H_U^j/U'_0 is β_j^*. We show $\tilde{U}_j \subset \tilde{U}_{j+1}$. Let $cU'_0 \times d\Gamma''_j \subset \tilde{U}_j$. Then β_j makes the assignment $\beta_j : cU'_0 \mapsto d\Gamma''_j$, and β_j^* makes the assignment

$$\beta_j^* : cU'_0 \mapsto d\Gamma''_{j+1}.$$

Since the restriction of β_{j+1} to H_U^j/U'_0 is β_j^*, we have β_{j+1} makes the assignment

$$\beta_{j+1} : cU'_0 \mapsto d\Gamma''_{j+1}.$$

Then $cU'_0 \times d\Gamma''_{j+1} \subset \tilde{U}_{j+1}$. Since $cU'_0 \times d\Gamma''_j \subset cU'_0 \times d\Gamma''_{j+1}$, this means $\tilde{U}_j \subset \tilde{U}_{j+1}$. •

Remark: Note that if $\Gamma''_{j+1} = \Gamma''_j$, Figure 4 becomes trivial, i.e., $H_V^{j*} = H_V^j$ and $\beta_j^* = \beta_j$.

From Theorem 35, the conditions in Lemma 36 apply to $\tilde{G}$, and thus $\tilde{G}$ has the properties given in Lemma 36. This completes the analysis of $\tilde{G}$. We now give a synthesis result, a construction of a subdirect product group which is a shift group. We reuse the notation in Lemma 36; this should not be confusing.

Theorem 37 *Assume there is a group* H_U *with a normal chain*

$$\mathbf{1} = H_U^{-1} \lhd U'_0 = H_U^0 \lhd H_U^1 \lhd \cdots \lhd H_U^j \lhd \cdots \lhd H_U^{\ell-1} = H_U^\ell = H_U, \tag{78}$$

where each $H_U^j \lhd H_U$. *Assume there are groups* H_V *and* V_0'' *and normal chains*

$$\mathbf{1} = H_V^0 \lhd H_V^{0*} \lhd H_V^1 \lhd H_V^{1*} \lhd \cdots \lhd H_V^j \lhd H_V^{j*} \lhd \cdots \lhd H_V^{\ell-1} \lhd H_V^{\ell-1*} = H_V^\ell = H_V, \tag{79}$$

$$\mathbf{1} = \Gamma_0'' \lhd \Gamma_1'' \lhd \cdots \lhd \Gamma_j'' \lhd \cdots \lhd \Gamma_\ell'' = V_0'', \tag{80}$$

where each $H_V^j \lhd H_V$, *and each* $\Gamma_j'' \lhd H_V$ *and* $V_0'' \lhd H_V$, *such that* $H_V^j \cap V_0'' = \Gamma_j''$ *and* $H_V^{j*} = H_V^j \Gamma_{j+1}''$. *Assume there is an isomorphism* $\phi_j : H_U^j \to H_V^{j+1}$ *for* $-1 \le j < \ell$, *such that for* $0 \le j < \ell$, *the restriction of* ϕ_j *to* H_U^{j-1} *is* ϕ_{j-1}. *Assume the three normal chains* $\{H_U^j\}$, $\{H_V^j\}$, *and* $\{\Gamma_j''\}$ *are related such that for* $0 \le j < \ell$ *there is an isomorphism* β_{j+1},

$$\beta_{j+1} : \frac{H_U^{j+1}}{U_0'} \to \frac{H_V^{j+1}}{\Gamma_{j+1}''}, \tag{81}$$

whose restriction to H_U^j/U_0' *is the isomorphism* $\beta_j^* = \eta_j'' \circ \beta_j$ *shown in Figure 4, where*

$$\beta_j^* : H_U^j/U_0' \to H_V^{j*}/\Gamma_{j+1}'',$$

and η_j'' *is the isomorphism*

$$\eta_j'' : H_V^j/\Gamma_j'' \to H_V^{j*}/\Gamma_{j+1}''$$

given by (2) of Lemma 6 using $H_V^{j*} = H_V^j \Gamma_{j+1}''$ *in the hypothesis. Define isomorphism* β_0,

$$\beta_0 : \frac{H_U^0}{U_0'} \to \frac{H_V^0}{\Gamma_0''},$$

the trivial isomorphism $\beta_0 : \mathbf{1} \to \mathbf{1}$. *For* $0 \le j < \ell$, *let* $\tilde{U}_{j+1}$ *be the subdirect product of* $H_U^{j+1} \times H_V^{j+1}$ *implied by the isomorphism (81). Let* $\tilde{U}_0$ *be the subdirect product of* $H_U^0 \times H_V^0$ *implied by the isomorphism* β_0, *i.e.,* $\tilde{U}_0 = U_0' \times \mathbf{1}$. *Define* $\tilde{U}_{-1} \overset{\text{def}}{=} \mathbf{1} \times \mathbf{1}$; *define* $\tilde{H} \overset{\text{def}}{=} \tilde{U}_\ell$. *Then* $\tilde{H}$ *is a group with a shift structure* $(\{\tilde{U}_j\}, \tilde{V}_0, \tilde{\phi})$, *where* $\tilde{V}_0 \overset{\text{def}}{=} \mathbf{1} \times V_0''$ *and* $\tilde{\phi} : \tilde{H}/\tilde{V}_0 \to \tilde{H}/\tilde{U}_0$ *is an isomorphism closely related to* $\phi_{\ell-1}$. *(The precise connection is shown in the proof below.)*

Proof We need to show that $\tilde{H}$ is a group with a shift structure $(\{\tilde{U}_j\}, \tilde{V}_0, \tilde{\phi})$. First we show that $\tilde{U}_j \lhd \tilde{H}$ for $-1 \le j \le \ell$. By assumption we know that $H_U^j \lhd H_U$ and $H_V^j \lhd H_V$ for $0 \le j \le \ell$. Now suppose $(h_u, h_v) \in \tilde{H}$. Since $\tilde{U}_j$ is a subdirect product of $H_U^j \times H_V^j$, we have

$$(h_u, h_v)\tilde{U}^j(h_u, h_v)^{-1} \subset \tilde{U}^j.$$

Thus $\tilde{U}_j \lhd \tilde{H}$ for $0 \le j \le \ell$. Clearly $\tilde{U}_{-1} \lhd \tilde{H}$.

Applying Lemma 36 shows that $\tilde{U}_j \subset \tilde{U}_{j+1}$ for $0 \le j < \ell$. Clearly $\tilde{U}_{-1} \subset \tilde{U}_0$.

Since $\tilde{V}_0 = \mathbf{1} \times V_0''$ are all the elements with $\mathbf{1}$ in the first coordinate, we must have $\tilde{V}_0 \lhd \tilde{H}$.

We now show that there is an isomorphism $\tau : \tilde{H}/\tilde{V}_0 \to H_U$ such that the restriction of τ to $\tilde{U}_j\tilde{V}_0/\tilde{V}_0$ is

$$\tau(\tilde{U}_j\tilde{V}_0/\tilde{V}_0) = H_U^j$$

for $-1 \le j < \ell$. We know that $\tilde{H}$ is a subdirect product of $H_U \times H_V$. But $\mathbf{1} \times V_0''$ are all the elements in $\tilde{H}$ with identity $\mathbf{1}$ in the first coordinate. This shows there is an isomorphism

$$H_U \simeq \frac{\tilde{H}}{\mathbf{1} \times V_0''} = \frac{\tilde{H}}{\tilde{V}_0}.$$

Let $\tau : \tilde{H}/\tilde{V}_0 \to H_U$ be the corresponding isomorphism. A subgroup $\grave{H}$ of $\tilde{H}/\tilde{V}_0$ is just a collection of cosets of $\tilde{V}_0$,

$$\grave{H} = \{s\tilde{V}_0 | s\tilde{V}_0 \in \tilde{H}\}.$$

Each coset $s\tilde{V}_0$ is of the form $h_u \times h_v V_0''$ for some $h_u \in H_U$, $h_v \in H_V$. Thus $\tau(\grave{H})$ is just the projection of $\grave{H}$ onto the first coordinate h_u of each coset $s\tilde{V}_0 \in \grave{H}$.

Now fix j, $0 \le j < \ell$. We know that $\tilde{U}_j$ is a subdirect product of $H_U^j \times H_V^j$. Then by construction of $\tilde{H}$ we know that $\tilde{U}_j\tilde{V}_0$ must be a subdirect product of H_U^j and of some group $\bar{H}_V^j$ isomorphic to $\tilde{U}_j\tilde{V}_0/\tilde{U}_0$ such that $\bar{H}_V^j \supset H_V^j$. Thus we must have $\tau(\tilde{U}_j\tilde{V}_0/\tilde{V}_0) = H_U^j$. Clearly $\tau(\tilde{U}_{-1}\tilde{V}_0/\tilde{V}_0) = H_U^{-1}$.

We now show that there is an isomorphism $\xi : \tilde{H}/\tilde{U}_0 \to H_V$ such that the restriction of ξ to $\tilde{U}_j/\tilde{U}_0$ is

$$\xi(\tilde{U}_j/\tilde{U}_0) = H_V^j$$

for $0 \le j \le \ell$. We know that $\tilde{H}$ is a subdirect product of $H_V \times H_V$. But $U_0' \times \mathbf{1}$ are all the elements in $\tilde{U}_j$ with $\mathbf{1}$ in the second coordinate. This shows there is an isomorphism

$$H_V \simeq \frac{\tilde{H}}{U_0' \times \mathbf{1}} = \frac{\tilde{H}}{\tilde{U}_0}.$$

Let $\xi : \tilde{H}/\tilde{U}_0 \to H_V$ be the corresponding isomorphism. As for τ, for $\acute{H}$ a collection of cosets $\{s\tilde{U}_0 | s\tilde{U}_0 \in \tilde{H}\}$ of $\tilde{U}_0$, $\xi(\acute{H})$ is just the projection of $\acute{H}$ onto the second coordinate h_v of each coset $s\tilde{U}_0 = h_u U_0' \times h_v \in \acute{H}$. For $0 \le j \le \ell$, we know that $\tilde{U}_j$ is a subdirect product of $H_U^j \times H_V^j$. Thus we must have $\xi(\tilde{U}_j/\tilde{U}_0) = H_V^j$ for $0 \le j \le \ell$.

We now show that there is an isomorphism $\tilde{\phi} : \tilde{H}/\tilde{V}_0 \to \tilde{H}/\tilde{U}_0$ which makes $\tilde{H}$ into a shift group, where $\tilde{\phi}$ is closely related to $\phi_{\ell-1}$. From the assumptions in the theorem, we know there is an isomorphism $\phi_{\ell-1} : H_U \to H_V$. Thus using τ and ξ we have

$$\frac{\tilde{H}}{\tilde{V}_0} \overset{\tau}{\simeq} H_U \overset{\phi_{\ell-1}}{\simeq} H_V \overset{\xi}{\simeq} \frac{\tilde{H}}{\tilde{U}_0}. \tag{82}$$

This defines an isomorphism

$$\tilde{\phi} : \frac{\tilde{H}}{\tilde{V}_0} \to \frac{\tilde{H}}{\tilde{U}_0},$$

where $\tilde{\phi}$ is the composition $\xi^{-1} \circ \phi_{\ell-1} \circ \tau$. We now show that

$$\tilde{\phi}(\tilde{U}_j \tilde{V}_0/\tilde{V}_0) = \tilde{U}_{j+1}/\tilde{U}_0$$

for $-1 \leq j < \ell$. From the assumptions in the theorem, we have $\phi_{\ell-1}(H_U^j) = H_V^{j+1}$ for $-1 \leq j < \ell$. Then we have

$$\begin{aligned} \tilde{\phi}(\tilde{U}_j \tilde{V}_0/\tilde{V}_0) &= (\xi^{-1} \circ \phi_{\ell-1} \circ \tau)(\tilde{U}_j \tilde{V}_0/\tilde{V}_0) \\ &= \tilde{U}_{j+1}/\tilde{U}_0 \end{aligned}$$

for $-1 \leq j < \ell$. Thus $\tilde{\phi}$ is the desired isomorphism, and $\tilde{H}$ has a shift structure $(\{\tilde{U}_j\}, \tilde{V}_0, \tilde{\phi})$. •

We have just shown that Theorem 37 gives a shift group $\tilde{H}$ which is a subdirect product group. Consider a mapping $\zeta : \tilde{H} \to H$, which just regards each element $(h_u, h_v) \in \tilde{H}$ as a single element $h \in H$, i.e., $\zeta : (h_u, h_v) \mapsto h$. We require the assignment $\zeta : (1, 1) \mapsto \mathbf{1}$. Then H is a group and ζ is an isomorphism. Using the isomorphism ζ, we can convert the subdirect product group $\tilde{H}$ into an abstract shift group H.

Proposition 38 *The group $\tilde{H}$ found by Theorem 37 is a subdirect product of H_U and H_V and has a shift structure $(\{\tilde{U}_j\}, \tilde{V}_0, \tilde{\phi})$. Under the isomorphism $\tilde{H} \overset{\zeta}{\simeq} H$, the group H has a shift structure $(\{U_j\}, V_0, \phi)$ and $|U_0 \cap V_0| = 1$.*

Note that we can make a round trip by starting with G, using Theorem 35 to obtain $\tilde{G}$, then using Theorem 37 to obtain $\tilde{H} = \tilde{G}$, and finally Proposition 38 to obtain $H = G$. Thus we can obtain any shift group G by starting with the description in Theorem 37.

We now simplify Theorem 37 further. From Theorem 37 we know that if $\tilde{H}$ is a shift group, there is an isomorphism $\phi_{\ell-1} : H_U^{\ell-1} \to H_V^{\ell}$ or just $\phi_{\ell-1} : H_U \to H_V$. This means that H_U and H_V are essentially the same. Thus the sequence of groups $\{H_V^{j*}\}$ in H_V corresponds to a dual sequence $\{H_U^{j*}\}$ in H_U. We let subgroup H_U^{j*} in H_U correspond to subgroup H_V^{j+1*} in H_V so that $\phi_{\ell-1}(H_U^{j*}) \overset{\text{def}}{=} H_V^{j+1*}$ for $-1 \leq j < \ell - 1$. Then we can find a refinement of the normal chain $\{H_U^j\}$ in (78):

$$\begin{aligned} \mathbf{1} = H_U^{-1} \lhd H_U^{-1*} \lhd U_0' = H_U^0 \lhd H_U^{0*} \lhd H_U^1 \lhd H_U^{1*} \lhd \cdots \\ \lhd H_U^j \lhd H_U^{j*} \lhd \cdots \lhd H_U^{\ell-2} \lhd H_U^{\ell-2*} = H_U^{\ell-1} = H_U^{\ell} = H_U, \end{aligned} \tag{83}$$

where $\phi_{\ell-1}(H_U^{j*}) = H_V^{j+1*}$ for $-1 \leq j < \ell - 1$, and each $H_U^{j*} \lhd H_U^{j+1}$ for $-1 \leq j < \ell - 1$. Note that since $H_V^{\ell-1} \lhd H_V^{\ell-1*} = H_V^{\ell}$, we have $H_U^{\ell-2} \lhd H_U^{\ell-2*} = H_U^{\ell-1}$ as shown.

The normal chain $\{\Gamma_j''\}$ in H_V corresponds to a dual chain $\{\Gamma_j'\}$ in H_U. We let subgroup Γ_j' in H_U correspond to subgroup Γ_{j+1}'' in H_V so that $\phi_{\ell-1}(\Gamma_j') \overset{\text{def}}{=} \Gamma_{j+1}''$ for $-1 \leq j < \ell$. Let V_0'' in H_V correspond to V_0' in H_U, so that $\phi_{\ell-1}(V_0') = V_0''$. Then using $\phi_{\ell-1}$ and normal chain $\{\Gamma_j''\}$ in (80), we can find a normal chain

$$\mathbf{1} = \Gamma_{-1}' \lhd \Gamma_0' \lhd \Gamma_1' \lhd \cdots \lhd \Gamma_j' \lhd \cdots \lhd \Gamma_{\ell-2}' \lhd \Gamma_{\ell-1}' = V_0', \tag{84}$$

where $\phi_{\ell-1}(\Gamma_j') = \Gamma_{j+1}''$ and each $\Gamma_j' \lhd H_U$ and $V_0' \lhd H_U$ for $-1 \leq j < \ell$, such that $H_U^j \cap V_0' = \Gamma_j'$ for $-1 \leq j < \ell$, and $H_U^{j*} = H_U^j \Gamma_{j+1}'$ for $-1 \leq j < \ell - 1$. Since $\Gamma_{\ell-1}'' \lhd \Gamma_\ell'' = V_0''$, we have $\Gamma_{\ell-2}' \lhd \Gamma_{\ell-1}' = V_0'$ as shown. Since $\Gamma_0'' = \mathbf{1}$, we have $\Gamma_{-1}' = \mathbf{1}$.

Assume the two normal chains (83) and (84) are related such that for $0 \leq j < \ell$ there is an isomorphism α_{j+1},

$$\alpha_{j+1} : \frac{H_U^{j+1}}{U_0'} \to \frac{H_U^j}{\Gamma_j'}, \tag{85}$$

whose restriction to H_U^j/U_0' is the isomorphism $\alpha_j^* = \eta_{j-1}' \circ \alpha_j$, where

$$\alpha_j^* : H_U^j/U_0' \to H_U^{j-1*}/\Gamma_j',$$

and η_{j-1}' is the isomorphism

$$\eta_{j-1}' : H_U^{j-1}/\Gamma_{j-1}' \to H_U^{j-1*}/\Gamma_j'$$

given by (2) of Lemma 6 using $H_U^{j-1*} = H_U^{j-1}\Gamma_j'$ in the hypothesis (see Figure 5). Define α_0 to be the trivial isomorphism $\alpha_0 : H_U^0/U_0' \to H_U^{-1}/\Gamma_{-1}'$, or $\alpha_0 : \mathbf{1} \to \mathbf{1}$.

$$\begin{tikzcd} H_U^j/U_0' \arrow[r, "\alpha_j"] \arrow[dr, "\alpha_j^*"'] & H_U^{j-1}/\Gamma_{j-1}' \arrow[d, "\eta_{j-1}'"] \\ & H_U^{j-1*}/\Gamma_j' \end{tikzcd}$$

Figure 5: Commutative diagram.

Since H_U and H_V are essentially the same, this suggests that in the construction of $\tilde{H}$ we only need to use H_U. We now show that we can recover $\tilde{H}$ in Theorem 37 by using just the two normal chains (83) and (84), isomorphism $\phi_{\ell-1}$ from Theorem 37, and isomorphism α_{j+1} in (85).

Theorem 39 *Using the normal chain $\{H_U^j, H_U^{j*}\}$ in (83), $\{\Gamma_j'\}$ in (84), isomorphism α_{j+1} in (85), and isomorphism $\phi_{\ell-1}$ from Theorem 37, we can recover $\tilde{H}$ in Theorem 37.*

Proof Clearly we can recover $\{H_U^j\}$ in (78) from the refinement in (83). Applying $\phi_{\ell-1}$ to each term in (83) we can recover $\{H_V^j\}$ in (79). We know that $H_U^j \lhd H_U$ for $-1 \leq j \leq \ell$. Since $\phi_{\ell-1}(H_U) = H_V$, we have $H_U^j \lhd H_U$ if and only if $\phi_{\ell-1}(H_U^j) = H_V^{j+1} \lhd H_V$. Then $H_V^j \lhd H_V$ for $0 \leq j \leq \ell$. Similarly using (84) and $\phi_{\ell-1}$, we can recover $\{\Gamma_j''\}$ in (80). Apply $\phi_{\ell-1}$ to H_U^j and Γ_j' on the right hand side in (85); then we can recover β_{j+1} in (81). Similarly we can recover β_j^* from α_j^* and η_j'' from η_{j-1}'. Thus we have recovered all the assumptions in Theorem 37, and we can proceed to find $\tilde{H}$ as in Theorem 37. •

We now show that we can find a shift group isomorphic to $\tilde{H}$ by using just two normal chains and isomorphism α_{j+1}, without any overt isomorphism $\phi_{\ell-1}$.

Theorem 40 *Using the normal chain* $\{H_U^j, H_U^{j*}\}$ *in (83),* $\{\Gamma_j'\}$ *in (84), and isomorphism* α_{j+1} *in (85), we can recover a shift group* $\hat{H}$ *isomorphic to* $\tilde{H}$.

Proof Define $\hat{H}_V^{j+1} \overset{\text{def}}{=} H_U^j$ for $-1 \le j < \ell$, $\hat{H}_V^{j+1*} \overset{\text{def}}{=} H_U^{j*}$ for $-1 \le j < \ell-1$, $\hat{\Gamma}''_{j+1} \overset{\text{def}}{=} \Gamma'_j$ for $-1 \le j < \ell$, and $\hat{V}_0'' \overset{\text{def}}{=} V_0'$. For $0 \le j < \ell$, define the isomorphism $\hat{\beta}_{j+1}$,

$$\hat{\beta}_{j+1} : \frac{H_U^{j+1}}{U_0'} \to \frac{\hat{H}_V^{j+1}}{\hat{\Gamma}''_{j+1}}, \tag{86}$$

using α_{j+1} and the substitutions $\hat{H}_V^{j+1} = H_U^j$, $\hat{\Gamma}''_{j+1} = \Gamma'_j$ in the right hand side of (85). In the same way, define the isomorphisms $\hat{\beta}_j^*$ and $\hat{\eta}_j''$. Similarly define $\hat{\beta}_0$ using α_0. For $0 \le j < \ell$, let $\hat{U}_{j+1}$ be the subdirect product of $H_U^{j+1} \times \hat{H}_V^{j+1}$ implied by the isomorphism (86). Let $\hat{U}_0$ be the subdirect product of $\hat{H}_U^0 \times \hat{H}_V^0$ implied by the isomorphism $\hat{\beta}_0$, i.e., $\hat{U}_0 = U_0' \times \mathbf{1}$. Define $\hat{U}_{-1} = \mathbf{1} \times \mathbf{1}$; define $\hat{H} \overset{\text{def}}{=} \hat{U}_\ell$. Define the trivial isomorphism $\hat{\phi}_j : H_U^j \to \hat{H}_V^{j+1}$ for $-1 \le j < \ell$ by the assignment $h \mapsto h$, $h \in H_U^j$. Then all the conditions in Theorem 37 are met so we see that $\hat{H}$ is a group with a shift structure $(\{\hat{U}_j\}, \hat{V}_0, \hat{\phi})$, where $\hat{V}_0 \overset{\text{def}}{=} \mathbf{1} \times \hat{V}_0''$ and $\hat{\phi} : \hat{H}/\hat{V}_0 \to \hat{H}/\hat{U}_0$ is just the isomorphism $\hat{\phi}_{\ell-1}$.

We have $\hat{H}_V^{j+1}$ is isomorphic to the group H_V^{j+1} in Theorem 37, and in fact

$$\phi_{\ell-1}(H_U^j) = \phi_{\ell-1}(\hat{H}_V^{j+1}) = H_V^{j+1},$$

where $\phi_{\ell-1}$ is the isomorphism in Theorem 37. Similarly $\hat{\Gamma}''_{j+1} \simeq \Gamma''_{j+1}$ since

$$\phi_{\ell-1}(\Gamma'_j) = \phi_{\ell-1}(\hat{\Gamma}''_{j+1}) = \Gamma''_{j+1}.$$

Thus $\hat{U}_{j+1}$, implied by the isomorphism $\hat{\beta}_{j+1}$ in (86), is isomorphic to $\tilde{U}_{j+1}$, implied by the isomorphism β_{j+1} in (81). Then $\hat{H} \simeq \tilde{H}$. •

Previously we have shown that given any reduced shift group G, we can use Theorem 35 to obtain a subdirect product group $\tilde{G}$ which is a shift group. Then we can use Theorem 37 to obtain $\tilde{H} = \tilde{G}$, and finally Proposition 38 to obtain $H = G$. Thus we can obtain any reduced shift group G by starting with the description in Theorem 37. In Theorem 40, we have shown that we can obtain a shift group $\hat{H}$ such that $\hat{H} \simeq \tilde{H}$. Using Proposition 38, the subdirect product group $\hat{H}$ can be converted into an abstract shift group H'. It is easy to show that $H' \simeq H = G$. Thus using the approach in Theorem 40, we can find all reduced shift groups G up to isomorphism.

Having found shift group H', it is clear that isomorphism is a sufficient condition to delineate the shift structure of any group G isomorphic to H'. The following proposition shows that if two groups are isomorphic and one of them is a shift group, then the other is a shift group and there is a 1-1 correspondence between their shift structures. Thus Theorem 40 can effectively find the shift structure of all reduced shift groups G.

Proposition 41 *Let* $\phi : G \to H$ *be an isomorphism. Then* G *is a shift group with a shift structure* $(\{X_j\}, Y_0, \varphi)$ *if and only if* H *is a shift group with a shift structure* $(\{U_j\}, V_0, \varphi')$, *where* $U_j = \phi(X_j)$, $V_0 = \phi(Y_0)$, *and the diagrams in Figure 6 commute. In Figure 6,* $\phi_1 : G/Y_0 \to H/V_0$ *is an isomorphism naturally induced by* $\phi : G \to H$, *and* $\phi_2 : G/X_0 \to H/U_0$ *is an isomorphism naturally induced by* ϕ.

$$\begin{tikzcd}
G/Y_0 \arrow[r, "\varphi"] \arrow[d, "\phi_1"'] & G/X_0 \arrow[d, "\phi_2"] \\
H/V_0 \arrow[r, "\varphi'"] & H/U_0
\end{tikzcd}$$

$$\begin{tikzcd}
X_j Y_0/Y_0 \arrow[r, "\varphi"] \arrow[d, "\phi_1"'] & X_{j+1}/X_0 \arrow[d, "\phi_2"] \\
U_j V_0/V_0 \arrow[r, "\varphi'"] & U_{j+1}/U_0
\end{tikzcd}$$

Figure 6: Commutative diagrams.

Of course the group H_U in Theorems 39 and 40 is the state group of shift group $\tilde{H}$ and $\hat{H}$, respectively. This gives the following result.

Theorem 42 *A group* H_U *is the state group of a shift group that is a subdirect product group if and only if*

(i) there is a normal chain

$$\mathbf{1} = H_U^{-1} \lhd H_U^{-1*} \lhd U_0' = H_U^0 \lhd H_U^{0*} \lhd H_U^1 \lhd H_U^{1*} \lhd \cdots \lhd H_U^j \lhd H_U^{j*} \lhd \cdots \lhd H_U^{\ell-2} \lhd H_U^{\ell-2*} = H_U^{\ell-1} = H_U^\ell = H_U, \tag{87}$$

where each $H_U^j \lhd H_U$;

(ii) there is a normal chain

$$\mathbf{1} = \Gamma'_{-1} \lhd \Gamma'_0 \lhd \Gamma'_1 \lhd \cdots \lhd \Gamma'_j \lhd \cdots \lhd \Gamma'_{\ell-2} \lhd \Gamma'_{\ell-1} = V_0',$$

where each $\Gamma'_j \lhd H_U$ *for* $-1 \le j < \ell$, *such that* $H_U^j \cap V'_0 = \Gamma'_j$ *for* $-1 \le j < \ell$, *and* $H_U^{j*} = H_U^j \Gamma'_{j+1}$ *for* $-1 \le j < \ell - 1$;

(iii) for $0 \le j < \ell$, *there is an isomorphism* α_{j+1},

$$\alpha_{j+1} : \frac{H_U^{j+1}}{U'_0} \to \frac{H_U^j}{\Gamma'_j}, \tag{88}$$

whose restriction to H_U^j/U'_0 *is the isomorphism* $\alpha_j^* = \eta'_{j-1} \circ \alpha_j$, *where*

$$\alpha_j^* : H_U^j/U'_0 \to H_U^{j-1*}/\Gamma'_j,$$

and η'_{j-1} *is the isomorphism*

$$\eta'_{j-1} : H_U^{j-1}/\Gamma'_{j-1} \to H_U^{j-1*}/\Gamma'_j$$

given by (2) of Lemma 6 using $H_U^{j-1*} = H_U^{j-1}\Gamma'_j$ *in the hypothesis. Define* α_0 *to be the trivial isomorphism* $\alpha_0 : H_U^0/U'_0 \to H_U^{-1}/\Gamma'_{-1}$, *or* $\alpha_0 : \mathbf{1} \to \mathbf{1}$.

Moreover we can find shift groups associated with H_U *as in Theorems 39 and 40; these shift groups are isomorphic.*

Note that in (iii) of Theorem 42, the case $j = \ell - 1$ is trivial once we have obtained $j = \ell - 2$. For $j = \ell - 1$, we are required to find an isomorphism

$$\alpha_\ell : H_U^\ell/U'_0 \to H_U^{\ell-1}/\Gamma'_{\ell-1},$$

whose restriction to $H_U^{\ell-1}/U'_0$ is the isomorphism $\alpha_{\ell-1}^* = \eta'_{\ell-2} \circ \alpha_{\ell-1}$, where

$$\alpha_{\ell-1}^* : H_U^{\ell-1}/U'_0 \to H_U^{\ell-2*}/\Gamma'_{\ell-1},$$

and $\eta'_{\ell-2}$ is the isomorphism given by (2) of Lemma 6 using $H_U^{\ell-2*} = H_U^{\ell-2}\Gamma'_{\ell-1}$ in the hypothesis. But the isomorphism $\eta'_{\ell-2}$ is easy to obtain from $H_U^{\ell-2*}$. And the case $j = \ell - 2$ in (iii) gives an isomorphism

$$\alpha_{\ell-1} : H_U^{\ell-1}/U'_0 \to H_U^{\ell-2}/\Gamma'_{\ell-2}.$$

Using $\alpha_{\ell-1}$ and $\eta'_{\ell-2}$ we can obtain $\alpha_{\ell-1}^*$. Now since $H_U^{\ell-1} = H_U^\ell$ and $H_U^{\ell-2*} = H_U^{\ell-1}$, we can trivially obtain α_ℓ by setting $\alpha_\ell = \alpha_{\ell-1}^*$. Thus the case $j = \ell - 1$ in (iii) can be eliminated. In addition, the group H_U^ℓ in (87) is now extraneous and can be eliminated. This gives the following corollary.

Corollary 43 *A group* H_U *is the state group of a shift group that is a subdirect product group if and only if*

(i) there is a normal chain

$$\mathbf{1} = H_U^{-1} \lhd H_U^{-1*} \lhd U'_0 = H_U^0 \lhd H_U^{0*} \lhd H_U^1 \lhd H_U^{1*} \lhd \cdots \lhd H_U^j \lhd H_U^{j*} \lhd \cdots \lhd H_U^{\ell-2} \lhd H_U^{\ell-2*} = H_U^{\ell-1} = H_U, \tag{89}$$

where each $H_U^j \lhd H_U$;

(ii) there is a normal chain

$$\mathbf{1} = \Gamma'_{-1} \lhd \Gamma'_0 \lhd \Gamma'_1 \lhd \cdots \lhd \Gamma'_j \lhd \cdots \lhd \Gamma'_{\ell-2} \lhd \Gamma'_{\ell-1} = V'_0,$$

where each $\Gamma'_j \lhd H_U$ *for* $-1 \le j < \ell$, *such that* $H_U^j \cap V'_0 = \Gamma'_j$ *for* $-1 \le j < \ell$, *and* $H_U^{j*} = H_U^j \Gamma'_{j+1}$ *for* $-1 \le j < \ell - 1$;

(iii) for $0 \le j < \ell - 1$, *there is an isomorphism* α_{j+1},

$$\alpha_{j+1} : \frac{H_U^{j+1}}{U'_0} \to \frac{H_U^j}{\Gamma'_j}, \tag{90}$$

whose restriction to H_U^j/U'_0 *is the isomorphism* $\alpha_j^* = \eta'_{j-1} \circ \alpha_j$, *where*

$$\alpha_j^* : H_U^j/U'_0 \to H_U^{j-1*}/\Gamma'_j,$$

and η'_{j-1} *is the isomorphism*

$$\eta'_{j-1} : H_U^{j-1}/\Gamma'_{j-1} \to H_U^{j-1*}/\Gamma'_j$$

given by (2) of Lemma 6 using $H_U^{j-1*} = H_U^{j-1}\Gamma'_j$ *in the hypothesis. Define* α_0 *to be the trivial isomorphism* $\alpha_0 : H_U^0/U'_0 \to H_U^{-1}/\Gamma'_{-1}$, *or* $\alpha_0 : \mathbf{1} \to \mathbf{1}$.

Thus we can find all reduced shift groups G up to isomorphism by first finding all state groups H_U with the properties in Corollary 43, and then finding associated shift groups as in Theorem 40.

Note that even though $|X_0 \cap Y_0| = 1$ for G, we do not necessarily have $|U'_0 \cap V'_0| = 1$ for H_U. From (ii) of Corollary 43, we have $H_U^0 \cap V'_0 = \Gamma'_0$, which implies $U'_0 \cap V'_0 = \Gamma'_0$. Note that the state group has one less degree of freedom than the shift group; i.e., we have $H_U^{\ell-1} = H_U$. We can think of the state group as being "$\ell - 1$-controllable" [2].

Corollary 43 suggests a method to construct any state group H_U. We start with a group U'_0 and then construct a chain of groups H_U^j that converges to $H_U^{\ell-2}$; then we find $H_U^{\ell-2*} = H_U$. Roughly, we can do this as follows (in the rough sketch here, we neglect any discussion of normality requirements). Let $H_U^0 = U'_0$ and define $\Gamma'_{-1} \overset{\text{def}}{=} \mathbf{1}$. Then $\alpha_0 : H_U^0/U'_0 \to H_U^{-1}/\Gamma'_{-1}$, which is just the isomorphism $\alpha_0 : \mathbf{1} \to \mathbf{1}$. We have $H_U^{-1*} = H_U^{-1}\Gamma'_0 = \Gamma'_0$. Thus we have obtained H_U^0, Γ'_0, and α_0.

In general assume we have found H_U^j, Γ'_j, and an isomorphism α_j. We now show how to find H_U^{j+1}, Γ'_{j+1}, and an isomorphism α_{j+1} that satisfies the restrictions in (iii) of Corollary 43. Please refer to Figure 7 where isomorphism α_j is shown in the bottom line. Note that subgroup H_U^{j-1*} of H_U^j satisfies $H_U^{j-1*} = H_U^{j-1}\Gamma'_j$. Then by (2) of Lemma 6 there is an isomorphism η'_{j-1},

$$\eta'_{j-1} : H_U^{j-1}/\Gamma'_{j-1} \to H_U^{j-1*}/\Gamma'_j.$$

This gives an isomorphism α_j^*,

$$\alpha_j^* : H_U^j/U'_0 \to H_U^{j-1*}/\Gamma'_j,$$

which is the next line of Figure 7. Now construct a group $H_U^{j*} = H_U^j \Gamma'_{j+1}$, where $\Gamma'_{j+1} \supset \Gamma'_j$, such that H_U^{j*} is an extension of U'_0 by $\dot{H}/\Gamma'_j$, where

$$\frac{H_U^{j-1*}}{\Gamma'_j} \subset \frac{\dot{H}}{\Gamma'_j} \subset \frac{H_U^j}{\Gamma'_j}.$$

In other words there is an isomorphism

$$\alpha_j^{**} : \frac{H_U^{j*}}{U'_0} \to \frac{\dot{H}}{\Gamma'_j},$$

which is the next line of Figure 7. We require that the restriction of α_j^{**} to H_U^j/U'_0 is the isomorphism α_j^*. Now find a group H_U^{j+1} such that $H_U^{j+1} \supset H_U^{j*}$ and H_U^{j+1} is an extension of U'_0 by H_U^j/Γ'_j; in other words there is an isomorphism

$$\alpha_{j+1} : \frac{H_U^{j+1}}{U'_0} \to \frac{H_U^j}{\Gamma'_j},$$

which is the top line in Figure 7. We require that the restriction of α_{j+1} to H_U^{j*}/U'_0 is the isomorphism α_j^{**}. In general this restriction is easy to meet since $H_U^{j+1} \supset H_U^{j*}$.

Thus we have obtained H_U^{j+1}, Γ'_{j+1}, and an isomorphism α_{j+1} that meets the restrictions in (iii) of Corollary 43. Continuing in this way gives $H_U^{\ell-2}$, $\Gamma'_{\ell-2}$, and isomorphism

$$\alpha_{\ell-2} : H_U^{\ell-2}/U'_0 \to H_U^{\ell-3}/\Gamma'_{\ell-3}.$$

In the last step, the top two lines of Figure 7 are the same, and the algorithm becomes degenerate. We have $H_U^{\ell-2*} = H_U^{\ell-1}$, $\dot{H} = H_U^{\ell-2}$, and $\alpha_{\ell-2}^{**} = \alpha_{\ell-1}$. First find

$$\alpha_{\ell-2}^* : H_U^{\ell-2}/U'_0 \to H_U^{\ell-3*}/\Gamma'_{\ell-2}.$$

Next construct a group $H_U^{\ell-2*} = H_U^{\ell-2}\Gamma'_{\ell-1}$ such that there is an isomorphism

$$\alpha_{\ell-2}^{**} : \frac{H_U^{\ell-2*}}{U'_0} \to \frac{H_U^{\ell-2}}{\Gamma'_{\ell-2}}.$$

We require that the restriction of $\alpha_{\ell-2}^{**}$ to $H_U^{\ell-2}/U'_0$ is $\alpha_{\ell-2}^*$. Again, since the last step is degenerate, $\alpha_{\ell-2}^{**}$ is $\alpha_{\ell-1}$ and $H_U^{\ell-2*}$ is $H_U^{\ell-1}$, which is just state group H_U.

$$\begin{array}{rlcl} \alpha_{j+1}: & H_U^{j+1}/U'_0 & \to & H_U^j/\Gamma'_j \\ \alpha_j^{**}: & H_U^{j*}/U'_0 & \to & \dot{H}/\Gamma'_j \\ \alpha_j^*: & H_U^j/U'_0 & \to & H_U^{j-1*}/\Gamma'_j \\ \alpha_j: & H_U^j/U'_0 & \to & H_U^{j-1}/\Gamma'_{j-1} \end{array}$$

Figure 7: Isomorphisms and groups used in construction of state group H_U.

For shift group G, we saw that X_0 and the normal chain $\{X_j \cap Y_0\}$ were related. This suggests that for a state group, U'_0 and $\{\Gamma'_j\}$ are related. We now prove this result. This approach shows finer details of the group H_U and gives a more elaborate version of Figure 7, allowing us to improve Corollary 43 and the algorithm.

Lemma 44 *Let H_U be the state group of a shift group. Fix j, $-1 \le j < \ell - 2$. If there is a normal chain*

$$H_U^{j+1} = Q_{j+1}^0 \lhd Q_{j+1}^1 \lhd Q_{j+1}^2 \lhd \cdots \lhd Q_{j+1}^{p-1} \lhd Q_{j+1}^p = H_U^{j+2}, \tag{91}$$

then there is a normal chain

$$H_U^j \lhd Q_j^a \lhd \cdots \lhd Q_j^b \lhd Q_j^0 \lhd Q_j^1 \lhd Q_j^2 \lhd \cdots \lhd Q_j^{p-1} \lhd Q_j^p = H_U^{j+1}, \tag{92}$$

where $Q_j^0 = H_U^{j*}$ and the normal chain

$$H_U^j \lhd Q_j^a \lhd \cdots \lhd Q_j^b \lhd Q_j^0 \tag{93}$$

is an arbitrary refinement of the trivial normal chain $H_U^j \lhd Q_j^0$. We have $H_U^j = Q_j^0$ if and only if $H_U^j = H_U^{j*}$; in this case any refinement in (93) is trivial. Although there is no restriction on the choice of the normal chain in (93), there are dependent relations among the Q_j^n and Q_{j+1}^n, $0 \le n \le p$. We have

$$\frac{Q_j^n}{Q_j^m} \simeq \frac{Q_{j+1}^n}{Q_{j+1}^m} \tag{94}$$

for m, n satisfying $0 \le m \le n \le p$. Moreover $Q_j^n \lhd H_U$ if $Q_{j+1}^n \lhd H_U$, for n satisfying $0 \le n \le p$. In addition, Q_j^n and Q_{j+1}^n are related by the isomorphism α_{j+2},

$$\alpha_{j+2}(Q_{j+1}^n/U'_0) = Q_j^n/\Gamma'_{j+1}, \tag{95}$$

for n satisfying $0 \le n \le p$.

Conversely, if there is a normal chain as in (92) with $Q_j^0 = H_U^{j*}$, then there is a normal chain as in (91), and $Q_{j+1}^n \lhd H_U$ if $Q_j^n \lhd H_U$, for n satisfying $0 \le n \le p$, and properties (94)-(95) hold.

Proof Fix j, $-1 \le j < \ell - 2$. We first show that if (91) holds, then (92) holds. As in (91), let

$$Q_{j+1}^0 \lhd Q_{j+1}^1 \lhd Q_{j+1}^2 \lhd \cdots \lhd Q_{j+1}^p$$

be a normal chain with each $Q_{j+1}^n \lhd H_U$. We know $U'_0 \lhd H_U$ and $U'_0 \subset Q_{j+1}^0$. Then from the correspondence theorem, there is a normal chain

$$\frac{Q_{j+1}^0}{U'_0} \lhd \frac{Q_{j+1}^1}{U'_0} \lhd \frac{Q_{j+1}^2}{U'_0} \lhd \cdots \lhd \frac{Q_{j+1}^p}{U'_0}$$

where

$$\frac{Q_{j+1}^n/U'_0}{Q_{j+1}^m/U'_0} \simeq \frac{Q_{j+1}^n}{Q_{j+1}^m}, \tag{96}$$

for $m \ge 0, n \ge 0$ satisfying $0 \le m \le n \le p$, and each $Q_{j+1}^n/U'_0 \lhd H_U/U'_0$.

Since for a state group there is an isomorphism $\alpha_{j+2} : H_U^{j+2}/U_0' \to H_U^{j+1}/\Gamma'_{j+1}$, for each n, $0 \le n \le p$, there is a subgroup $\dot{Q}_j^n/\Gamma'_{j+1}$ such that $\alpha_{j+2}(Q_{j+1}^n/U_0') = \dot{Q}_j^n/\Gamma'_{j+1}$. Thus the isomorphism α_{j+2} gives a normal chain

$$\frac{\dot{Q}_j^0}{\Gamma'_{j+1}} \lhd \frac{\dot{Q}_j^1}{\Gamma'_{j+1}} \lhd \frac{\dot{Q}_j^2}{\Gamma'_{j+1}} \lhd \cdots \lhd \frac{\dot{Q}_j^p}{\Gamma'_{j+1}}, \tag{97}$$

where each $\dot{Q}_j^n/\Gamma'_{j+1} \lhd H_U^{j+1}/\Gamma'_{j+1}$, and

$$\frac{\dot{Q}_j^n/\Gamma'_{j+1}}{\dot{Q}_j^m/\Gamma'_{j+1}} \simeq \frac{Q_{j+1}^n/U_0'}{Q_{j+1}^m/U_0'}. \tag{98}$$

Since H_U is a state group, we have $\dot{Q}_j^0/\Gamma'_{j+1} = H_U^{j*}/\Gamma'_{j+1}$ and $\dot{Q}_j^p/\Gamma'_{j+1} = H_U^{j+1}/\Gamma'_{j+1}$.

Consider the natural map $\nu_{j+1} : H_U^{j+1} \to H_U^{j+1}/\Gamma'_{j+1}$ defined by the assignment $h \mapsto h\Gamma'_{j+1}$. Define $Q_j^n \overset{\text{def}}{=} (\nu_{j+1})^{-1}(\dot{Q}_j^n/\Gamma'_{j+1})$. Then $Q_j^0 = H_U^{j*}$ and $Q_j^p = H_U^{j+1}$. Then using (97) and the correspondence theorem, we have a normal chain

$$Q_j^0 \lhd Q_j^1 \lhd Q_j^2 \lhd \cdots \lhd Q_j^p, \tag{99}$$

where

$$\frac{Q_j^n}{Q_j^m} \simeq \frac{\dot{Q}_j^n/\Gamma'_{j+1}}{\dot{Q}_j^m/\Gamma'_{j+1}}. \tag{100}$$

Since $Q_j^0 = H_U^{j*}$, we have $H_U^j \subset Q_j^0$, and combining this with (99) gives (92). From the correspondence theorem, we have each $Q_j^n \lhd H_U$. Collecting (96), (98), and (100) gives (94). Finally we have that (95) holds by construction.

Now assume (92) holds. We can show that (91) holds by essentially reversing the above steps. •

We see there are two cases to consider in Lemma 44 depending on whether $H_U^{j*} = H_U^j$ or $H_U^{j*} >> H_U^j$. Formally, we introduce a parameter ϵ_j for $-1 \le j < \ell - 1$. We set $\epsilon_j = 1$ if $H_U^{j*} >> H_U^j$, and $\epsilon_j = 0$ if $H_U^{j*} = H_U^j$.

Note that parameter ϵ_j is not the same as parameter ε_j. We have $H_U^{j*} >> H_U^j$ if and only if $H_V^{j+1*} >> H_V^{j+1}$. Therefore $H_U^{j*} >> H_U^j$ if and only if $\tilde{U}_{j+1}^* >> \tilde{U}_{j+1}$ in $\tilde{H}$. Under the isomorphism $\tilde{H} \overset{\zeta}{\simeq} H$, we have $\tilde{U}_{j+1}^* >> \tilde{U}_{j+1}$ if and only if $U_{j+1}^* >> U_{j+1}$ in H. Therefore ϵ_j corresponds to ε_{j+1}. Note that $\epsilon_{\ell-2} = \varepsilon_{\ell-1} = 1$ always. We have $\epsilon_{-1} = \varepsilon_0$. We have $\epsilon_{-1} = 0$ if and only if $\Gamma_0' = \mathbf{1}$. We always have $\varepsilon_{-1} = 0$ since $U_{-1}^* = U_0 \cap V_0 = \mathbf{1}$ for a reduced shift group.

In the next theorem, we use Lemma 44 to find a refinement of (87). It is convenient to write the refinement using slightly different notation than in Lemma 44. Thus in place of (91), we write the portion of the refinement between H_U^{j+1} and H_U^{j+2} as

$$\begin{aligned} H_U^{j+1} = H_U^{j+1,(k_{j+1})} \lhd H_U^{j+1,(k_{j+1}+1)} \lhd H_U^{j+1,(k_{j+1}+2)} \lhd \cdots \\ \lhd H_U^{j+1,(\ell'-1)} \lhd H_U^{j+1,(\ell')} = H_U^{j+2}, \end{aligned} \tag{101}$$

where k_{j+1} and ℓ' are positive integers. Using (101) in Lemma 44, we obtain the portion of the refinement between H_U^j and H_U^{j+1} as

$$\begin{aligned} H_U^j \lhd H_U^{j,(k_{j+1})} \lhd H_U^{j,(k_{j+1}+1)} \lhd H_U^{j,(k_{j+1}+2)} \lhd \cdots \\ \lhd H_U^{j,(\ell'-1)} \lhd H_U^{j,(\ell')} = H_U^{j+1}, \end{aligned} \tag{102}$$

where $H_U^{j,(k_{j+1})} = H_U^{j*}$. We only use Lemma 44 for a trivial refinement in (93), that is, when $H_U^j = Q_j^a = \cdots = Q_j^b$. In (102), we have $H_U^{j,(k_{j+1})} = H_U^{j*}$ if $\epsilon_j = 1$, and $H_U^{j,(k_{j+1})} = H_U^{j*} = H_U^j$ if $\epsilon_j = 0$.

In general for each j, $-1 \le j \le \ell - 2$, we define a refinement in which the superscript m of $H_U^{j,(m)}$ runs from integer k_j to integer ℓ'. For $0 \le j \le \ell - 1$, we define $H_U^{j-1,(\ell')} \overset{\text{def}}{=} H_U^j \overset{\text{def}}{=} H_U^{j,(k_j)}$; then $H_U^{\ell-2,(\ell')} = H_U^{\ell-1} = H_U^{\ell-1,(k_{\ell-1})}$. We also define $H_U^{-1} \overset{\text{def}}{=} H_U^{-1,(k_{-1})}$. In this notation, the portion of the refinement between H_U^j and H_U^{j+1} is

$$\begin{aligned} H_U^j = H_U^{j,(k_j)} \lhd H_U^{j,(k_j+1)} \lhd H_U^{j,(k_j+2)} \lhd \cdots \\ \lhd H_U^{j,(\ell'-1)} \lhd H_U^{j,(\ell')} = H_U^{j+1}. \end{aligned} \tag{103}$$

Comparing (102) and (103) shows that we must have $H_U^j = H_U^{j,(k_j)} = H_U^{j,(k_{j+1})} = H_U^{j*}$ if $\epsilon_j = 0$ and $H_U^{j,(k_j+1)} = H_U^{j,(k_{j+1})} = H_U^{j*}$ if $\epsilon_j = 1$. This means $k_j + \epsilon_j = k_{j+1}$. If we use the above procedure and apply Lemma 44 recursively starting with the normal chain

$$H_U^{\ell-2} = H_U^{\ell-2,(k_{\ell-2})} \lhd H_U^{\ell-2,(\ell')} = H_U^{\ell-1} = H_U,$$

we obtain

$$k_j = \ell' - \sum_{j \le i < \ell-1} \epsilon_i \tag{104}$$

for $-1 \le j < \ell - 1$. Define

$$\ell' \overset{\text{def}}{=} \sum_{-1 \le i < \ell-1} \epsilon_i.$$

Then from (104) we see $k_{-1} = 0$. If $j = \ell - 1$, we define $k_j = k_{\ell-1} \overset{\text{def}}{=} \ell'$ trivially. Thus as j runs from -1 to $\ell - 1$, k_j takes all values in the range $[0, \ell']$. Since

$$\sum_{-1 \le i < \ell-1} \epsilon_i = \sum_{-1 \le i < \ell} \varepsilon_i,$$

we see the above definition of ℓ' is consistent with the previous definition.

Theorem 45 *Let a shift group have a state group H_U. There is a refinement of $\{H_U^j\}$, and of the normal chain* *in (87), given by*

$$H_U^{-1} = H_U^{-1,(k_{-1})} \lhd \cdots \lhd H_U^{-1,(\ell')} = H_U^0 = H_U^{0,(k_0)} \lhd \cdots \lhd H_U^{j-1,(\ell')} = H_U^j = H_U^{j,(k_j)} \lhd H_U^{j,(k_j+1)} \lhd H_U^{j,(k_j+2)} \lhd \cdots \lhd H_U^{j,(\ell'-1)} \lhd H_U^{j,(\ell')} = H_U^{j+1} = H_U^{j+1,(k_{j+1})} \lhd \cdots \lhd H_U^{\ell-2,(k_{\ell-2})} \lhd H_U^{\ell-2,(k_{\ell-2}+1)} = H_U^{\ell-2,(\ell')} = H_U^{\ell-1} = H_U^{\ell-1,(k_\ell-1)} = H_U, \quad (105)$$

where each $H_U^{j,(k_j+n)} \lhd H_U$ *and* $H_U^{j,(k_j+1)} = H_U^{j*}$ *if* $\epsilon_j = 1$. *Moreover*

$$\frac{H_U^{-1,(k_j+n)}}{H_U^{-1,(k_j+m)}} \simeq \frac{H_U^{j,(k_j+n)}}{H_U^{j,(k_j+m)}} \quad (106)$$

for $-1 \le j < \ell - 1$ *and* m, n *satisfying* $k_j \le k_j + m \le k_j + n \le \ell'$. *In addition, the isomorphism* α_{j+2} *satisfies*

$$\alpha_{j+2}(H_U^{j+1,(k_{j+1}+n)}/U_0') = H_U^{j,(k_j+\epsilon_j+n)}/\Gamma_{j+1}' \quad (107)$$

for $-1 \le j < \ell - 2$ *and* n *satisfying* $k_{j+1} \le k_{j+1} + n \le \ell'$.

Proof Starting from the normal chain $H_U^{\ell-2} = H_U^{\ell-2,(k_{\ell-2})} \lhd H_U^{\ell-2,(\ell')} = H_U^{\ell-1}$, where $H_U^{\ell-2} \lhd H_U$ and $H_U^{\ell-1} \lhd H_U$, we can use Lemma 44 to go 'backwards' and for each j, $-1 \le j < \ell - 2$, obtain a normal chain from H_U^j to H_U^{j+1} as in (105), where each $H_U^{j,(k_j+n)} \lhd H_U$ for n satisfying $k_j \le k_j + n \le \ell'$, and $H_U^{j,(k_j+1)} = H_U^{j*}$ if $\epsilon_j = 1$.

Since $k_{j+1} = k_j + \epsilon_j$, we can restate (95) of Lemma 44 as in (107), for n satisfying $k_{j+1} \le k_{j+1} + n \le \ell'$.

It only remains to show (106). We can do this by induction. We assume (106) holds for $q + 1$, that is, we assume

$$\frac{H_U^{q+1,(k_j+n)}}{H_U^{q+1,(k_j+m)}} \simeq \frac{H_U^{j,(k_j+n)}}{H_U^{j,(k_j+m)}} \quad (108)$$

for $q + 1 \le j < \ell - 1$ and m, n satisfying $k_j \le k_j + m \le k_j + n \le \ell'$. Note that the left hand side of (108) is well defined since $k_{q+1} \le k_j$ for $q + 1 \le j$. Then we show (106) holds for q, that is, we show

$$\frac{H_U^{q,(k_j+n)}}{H_U^{q,(k_j+m)}} \simeq \frac{H_U^{j,(k_j+n)}}{H_U^{j,(k_j+m)}} \quad (109)$$

for $q \le j < \ell - 1$ and m, n satisfying $k_j \le k_j + m \le k_j + n \le \ell'$.

Assume that j satisfies $q + 1 \le j < \ell - 1$ and m, n satisfy $k_j \le k_j + m \le k_j + n \le \ell'$. Assume that (108) holds. We can write the portion of the normal chain in (105) between H_U^q and H_U^{q+1} as

$$H_U^q = H_U^{q,(k_q)} \lhd H_U^{q,(k_q+1)} \lhd H_U^{q,(k_q+2)} \lhd \cdots \lhd H_U^{q,(\ell'-1)} \lhd H_U^{q,(\ell')} = H_U^{q+1}, \quad (110)$$

and between H_U^{q+1} and H_U^{q+2} as

$$H_U^{q+1} = H_U^{q+1,(k_{q+1})} \lhd H_U^{q+1,(k_{q+1}+1)} \lhd H_U^{q+1,(k_{q+1}+2)} \lhd \cdots \lhd H_U^{q+1,(\ell'-1)} \lhd H_U^{q+1,(\ell')} = H_U^{q+2}. \quad (111)$$

Then using Lemma 44 with (111) in place of (91) and (110) in place of (92), we have from (94)

$$\frac{H_U^{q,(k_j+n)}}{H_U^{q,(k_j+m)}} \simeq \frac{H_U^{q+1,(k_j+n)}}{H_U^{q+1,(k_j+m)}}. \quad (112)$$

Note that all terms in (112) are well defined since $k_q \le k_{q+1} \le k_j$ for $q + 1 \le j$. Combining (112) with (108) gives

$$\frac{H_U^{q,(k_j+n)}}{H_U^{q,(k_j+m)}} \simeq \frac{H_U^{j,(k_j+n)}}{H_U^{j,(k_j+m)}}. \quad (113)$$

We know that (113) holds for $q + 1 \le j < \ell - 1$ and m, n satisfying $k_j \le k_j + m \le k_j + n \le \ell'$. But (113) also holds trivially for $j = q$. Then (113) holds for $q \le j < \ell - 1$ and m, n satisfying $k_j \le k_j + m \le k_j + n \le \ell'$, giving (109).

We start the induction by proving (109) for $q = \ell - 3$. But from Lemma 44, we know there are normal chains $H_U^{\ell-2} \lhd H_U^{\ell-1}$ and $H_U^{\ell-3} \lhd H_U^{\ell-3*} \lhd H_U^{\ell-2}$ with

$$\frac{H_U^{\ell-2}}{H_U^{\ell-3*}} \simeq \frac{H_U^{\ell-1}}{H_U^{\ell-2}}.$$

Rewriting this as

$$\frac{H_U^{\ell-3,(\ell')}}{H_U^{\ell-3,(k_{\ell-2})}} \simeq \frac{H_U^{\ell-2,(\ell')}}{H_U^{\ell-2,(k_{\ell-2})}}$$

gives (109) for $q = \ell - 3$. •

We can illustrate Theorem 45 as previously done for Theorem 11 in Figure 2.

We are particularly interested in the portion of the normal chain from H_U^{-1} to H_U^0:

$$H_U^{-1} = H_U^{-1,(k_{-1})} \lhd H_U^{-1,(k_{-1}+1)} \lhd \cdots \lhd H_U^{-1,(k_{-1}+n)} \lhd \cdots \lhd H_U^{-1,(\ell'-1)} \lhd H_U^{-1,(\ell')} = H_U^0. \quad (114)$$

In (114), the superscript m of $H_U^{-1,(m)}$ takes all values in the interval $[k_{-1}, \ell']$ or $[0, \ell']$. Using (104), for j satisfying $-1 \le j \le \ell - 1$, we know k_j takes all values in the interval $[0, \ell']$. Then for $-1 \le j \le \ell - 1$, the term $H_U^{-1,(k_j)}$ appears in (114), and we can make the definition

$$\Delta_j' \overset{\text{def}}{=} H_U^{-1,(k_j)}.$$

Then

$$H_U^{-1} = \Delta_{-1}' \lhd \Delta_0' \lhd \cdots \lhd \Delta_j' \lhd \cdots \lhd \Delta_{\ell-1}' = H_U^0 \quad (115)$$

is a refinement of (114) which at most just repeats terms in (114). Since each $H_U^{-1,(k_{-1}+n)} \lhd H_U$, we know that each $\Delta_j' \lhd H_U$.

Given a state group H_U, the normal chain in (105) is uniquely determined, and so the normal chains (114) and (115) are uniquely determined. We say the normal chain in (115) is a *signature chain* of state group H_U. We now give some properties of the signature chain.

Theorem 46 *Let a shift group have a state group H_U. Fix j, $-1 \leq j < \ell - 1$. The signature chain of the state group has the property that*

$$\frac{H_U^{j+1}}{H_U^j} \simeq \frac{H_U^0}{\Delta'_j}, \tag{116}$$

$$\frac{H_U^{j+1}}{H_U^{j*}} \simeq \frac{H_U^0}{\Delta'_{j+1}}, \tag{117}$$

and

$$\frac{H_U^{j*}}{H_U^j} \simeq \frac{\Delta'_{j+1}}{\Delta'_j}. \tag{118}$$

We have

$$\Delta'_0 = H_U^{-1*} = \Gamma'_0, \tag{119}$$

$$\frac{\Delta'_{j+1}}{\Delta'_j} \simeq \frac{\Gamma'_{j+1}}{\Gamma'_j}, \tag{120}$$

and

$$|\Delta'_{j+1}| = |\Gamma'_{j+1}|. \tag{121}$$

Proof Results (116)-(118) follow from (106) of Theorem 45 using the definition of Δ'_j.

We now show (119). We have $H_U^{-1,(k_{-1}+1)} = H_U^{-1*}$ if $\epsilon_{-1} = 1$, and $H_U^{-1,(k_{-1})} = H_U^{-1*} = H_U^{-1}$ if $\epsilon_{-1} = 0$. Also k_0 and k_{-1} are related by $k_0 = k_{-1} + \epsilon_{-1}$. Thus $H_U^{-1,(k_0)} = H_U^{-1*}$ if $\epsilon_{-1} = 1$ or $\epsilon_{-1} = 0$. But $\Delta'_0 = H_U^{-1,(k_0)}$ by definition, and $H_U^{-1*} = H_U^{-1}\Gamma'_0 = \Gamma'_0$ using (ii) of Theorem 42. Then (119) follows.

Now use Lemma 6 with $Q' = \Gamma'_j$; $Q = H_U^j$, $R' = \Gamma'_{j+1}$, and $R = H_U^{j*}$. The conditions in Lemma 6 are satisfied because H_U is a state group. Then (3) of Lemma 6 gives

$$\frac{H_U^{j*}}{H_U^j} \simeq \frac{\Gamma'_{j+1}}{\Gamma'_j}. \tag{122}$$

Combining (118) and (122) gives (120). Now use induction with (119) and (120) to obtain (121). •

Remark: Note from (120) that if $\Delta'_{-1} = \cdots = \Delta'_j = \mathbf{1}$ and $\Delta'_{j+1} \neq \mathbf{1}$, then $\Gamma'_{-1} = \cdots = \Gamma'_j = \mathbf{1}$ and $\Delta'_{j+1} \simeq \Gamma'_{j+1}$. Since $H_U^{\ell-2} << H_U^{\ell-2*}$, we always have $|\Delta'_{\ell-2}| < |\Delta'_{\ell-1}|$.

We have the following easy corollary of Theorem 46.

Corollary 47 *If H_U is a state group, the factor groups H_U^{j+1}/H_U^j in the normal chain $\{H_U^j\}$ are abelian if $U'_0 = H_U^0$ is abelian. In this case then, $\{H_U^j\}$ is a solvable series and H_U is solvable.*

We can now include the results of Theorem 45 and Theorem 46 in Corollary 43.

Theorem 48 *A group H_U is the state group of a shift group that is a subdirect product group if and only if*

(i) there is a normal chain

$$\begin{aligned} H_U^{-1} = H_U^{-1,(k_{-1})} \lhd \cdots \lhd H_U^{-1,(\ell')} = H_U^0 = H_U^{0,(k_0)} \lhd \cdots \\ \lhd H_U^{j-1,(\ell')} = H_U^j = H_U^{j,(k_j)} \lhd H_U^{j,(k_j+1)} \lhd H_U^{j,(k_j+2)} \lhd \cdots \\ \lhd H_U^{j,(\ell'-1)} \lhd H_U^{j,(\ell')} = H_U^{j+1} = H_U^{j+1,(k_{j+1})} \lhd \cdots \\ \lhd H_U^{\ell-2,(k_{\ell-2})} \lhd H_U^{\ell-2,(k_{\ell-2}+1)} = H_U^{\ell-2,(\ell')} = \\ H_U^{\ell-2*} = H_U^{\ell-1} = H_U, \end{aligned} \tag{123}$$

where each $H_U^{j,(k_j+n)} \lhd H_U$ and $H_U^{j,(k_j+1)} = H_U^{j*}$ if $\epsilon_j = 1$;

(ii) there is a refinement of the portion of the normal chain from $\mathbf{1} = H_U^{-1}$ to $U'_0 = H_U^0$, given by

$$\mathbf{1} = \Delta'_{-1} \lhd \Delta'_0 \lhd \Delta'_1 \lhd \cdots \Delta'_j \lhd \cdots \lhd \Delta'_{\ell-1} = U'_0 = H_U^0,$$

where each $\Delta'_j \lhd H_U$ and $\Delta'_j \overset{\text{def}}{=} H_U^{-1,(k_j)}$ for $-1 \leq j < \ell$;

(iii) there is a normal chain

$$\mathbf{1} = \Gamma'_{-1} \lhd \Gamma'_0 \lhd \Gamma'_1 \lhd \cdots \lhd \Gamma'_j \lhd \cdots \lhd \Gamma'_{\ell-2} \lhd \Gamma'_{\ell-1} = V'_0,$$

where each $\Gamma'_j \lhd H_U$ for $-1 \leq j < \ell$, such that $H_U^j \cap V'_0 = \Gamma'_j$ for $-1 \leq j < \ell$, and $H_U^{j*} = H_U^j \Gamma'_{j+1}$ for $-1 \leq j < \ell - 1$, and

$$\Gamma'_{j+1}/\Gamma'_j \simeq \Delta'_{j+1}/\Delta'_j$$

for $-1 \leq j < \ell - 1$;

(iv) for $0 \leq j < \ell - 1$, there is an isomorphism α_{j+1},

$$\alpha_{j+1} : \frac{H_U^{j+1}}{U'_0} \to \frac{H_U^j}{\Gamma'_j}, \tag{124}$$

whose restriction to H_U^j/U'_0 is the isomorphism $\alpha_j^* = \eta'_{j-1} \circ \alpha_j$, where

$$\alpha_j^* : H_U^j/U'_0 \to H_U^{j-1*}/\Gamma'_j,$$

and η'_{j-1} is the isomorphism

$$\eta'_{j-1} : H_U^{j-1}/\Gamma'_{j-1} \to H_U^{j-1*}/\Gamma'_j$$

given by (2) of Lemma 6 using $H_U^{j-1*} = H_U^{j-1}\Gamma'_j$ in the hypothesis; define α_0 to be the trivial isomorphism $\alpha_0 : H_U^0/U'_0 \to H_U^{-1}/\Gamma'_{-1}$, or $\alpha_0 : \mathbf{1} \to \mathbf{1}$;

(v) for $0 \leq j < \ell - 1$, the isomorphism α_{j+1} satisfies

$$\alpha_{j+1}(H_U^{j,(k_j+n)}/U'_0) = H_U^{j-1,(k_{j-1}+\epsilon_{j-1}+n)}/\Gamma'_j \tag{125}$$

for n satisfying $k_j \leq k_j + n \leq \ell'$.

We now restate Theorem 48 by combining (iv) and (v).

Corollary 49 *A group H_U is the state group of a shift group that is a subdirect product group if and only if (i), (ii), and (iii) of Theorem 48 hold, and*

(iv) for $0 \leq j < \ell - 1$ and n satisfying $k_j \leq k_j + n \leq \ell'$, there is an isomorphism $\alpha_j^{(k_j+n)}$, given by

$$\alpha_j^{(k_j+n)} : \frac{H_U^{j,(k_j+n)}}{U'_0} \to \frac{H_U^{j-1,(k_{j-1}+\epsilon_{j-1}+n)}}{\Gamma'_j}, \tag{126}$$

such that for $n = 1, \ldots, \ell' - k_j$, the restriction of $\alpha_j^{(k_j+n)}$ to $H_U^{j,(k_j+n-1)}/U_0'$ is $\alpha_j^{(k_j+n-1)}$. The isomorphism

$$\alpha_j^{(k_j)} : H_U^j/U_0' \to H_U^{j-1*}/\Gamma_j'$$

is the isomorphism $\alpha_j^{(k_j)} = \eta_{j-1}' \circ \alpha_{j-1}^{(\ell')}$, where η_{j-1}' is the isomorphism

$$\eta_{j-1}' : H_U^{j-1}/\Gamma_{j-1}' \to H_U^{j-1*}/\Gamma_j'$$

given by (2) of Lemma 6 using $H_U^{j-1*} = H_U^{j-1}\Gamma_j'$ in the hypothesis. For $j = 0$, note that $\alpha_0^{(k_0)} : H_U^0/U_0' \to H_U^{-1*}/\Gamma_0'$ is the trivial isomorphism $\alpha_0^{(k_0)} : \mathbf{1} \to \mathbf{1}$, and we define $\alpha_0^{(k_0)}$ this way.

Proof For $0 \leq j < \ell-1$ and n satisfying $k_j \leq k_j+n \leq \ell'$, we define $\alpha_j^{(k_j+n)}$ to be an isomorphism with domain and range as in (126) such that

$$\alpha_j^{(k_j+n)}(H_U^{j,(k_j+n)}/U_0') = \alpha_{j+1}(H_U^{j,(k_j+n)}/U_0').$$

Now note that $\alpha_j^{(k_j)}$ is just α_j^* and $\alpha_{j-1}^{(\ell')}$ is just α_j. •

5 Algorithms

Arpasi and Palazzo [12] have previously given an algorithm to construct a strongly controllable group code starting with a given group G (if it is possible). Sarvis and Trott [10] and Sindhushayana, Marcus, and Trott [11] have given algorithms to construct all homogeneous trellis codes and all homogeneous shifts, respectively. In this section, we give an algorithm to construct the state group of a shift group. Using the state group, it is easy to construct the strongly controllable shift group and group code. We start with the group U_0' and work up to state group H_U. This approach may have an advantage in constructing a Latin group code since we can specify a group U_0' with the desired properties at the start. In the approach here, all intermediate calculations take place inside the final group H_U, whereas the approach of [10, 11] uses a sequence of derivative codes or derived shifts which are indirectly related to the final group.

We give an algorithm to find all state groups H_U having a given U_0' and a given signature chain

$$\mathbf{1} = \Delta_{-1}' \lhd \Delta_0' \lhd \Delta_1' \lhd \cdots \Delta_j' \lhd \cdots \lhd \Delta_{\ell-1}' = U_0'.$$

Then it is easy to find the reduced shift group associated with H_U. The algorithm is loosely based on Algorithm 1 in version 1 of this paper. We can find a Latin shift group and Latin group code by modifying Algorithms 2 and 3 in version 1 of this paper.

The algorithm is just a literal implementation of Corollary 49. The algorithm has three parts, I, II, and III, which cover the index step range $j = -1, \ldots, \ell-2$. Part I is an initialization; this is index step $j = -1$. Part II is the main portion of the algorithm; it covers index steps $j = 0, \ldots, \ell-2$. Part III just states the final result.

Algorithm to find state group:

I. Pick a group U_0' and a normal chain

$$\mathbf{1} = \Delta_{-1}' \lhd \Delta_0' \lhd \Delta_1' \lhd \cdots \Delta_j' \lhd \cdots \lhd \Delta_{\ell-1}' = U_0' \quad (127)$$

where each $\Delta_j' \lhd U_0'$. Construct the parameters ϵ_j for $-1 \leq j < \ell-1$. Thus using (127), we set $\epsilon_j = 1$ if $|\Delta_{j+1}'|/|\Delta_j'| > 1$ and $\epsilon_j = 0$ if $|\Delta_{j+1}'|/|\Delta_j'| = 1$. There is a subsequence of (127),

$$\mathbf{1} = \Delta_{-1}' \lhd \cdots \lhd \Delta_m' \lhd \Delta_{m'}' \lhd \cdots \lhd \Delta_{\ell-1}' = U_0', \quad (128)$$

consisting of terms Δ_{m+1}' for which $\epsilon_m = 1$, or $|\Delta_{m+1}'|/|\Delta_m'| > 1$, and an initial term $\mathbf{1} = \Delta_{-1}'$. Define parameter ℓ',

$$\ell' \stackrel{\text{def}}{=} |\{j|\epsilon_j = 1, -1 \leq j < \ell-1\}|.$$

There are $\ell'+1$ terms in (128). We reindex the subscripts in (128) with integers $0, 1, \ldots, \ell'$ so that order is preserved, and define this to be the sequence

$$\mathbf{1} = H_U^{-1,(0)} \lhd H_U^{-1,(1)} \lhd \cdots \lhd H_U^{-1,(j)} \lhd H_U^{-1,(j+1)} \lhd \cdots \lhd H_U^{-1,(\ell')} = U_0'.$$

In other words, $H_U^{-1,(j)} = \Delta_m'$ if and only if $H_U^{-1,(j+1)} = \Delta_{m'}'$. Note that $H_U^{-1,(0)} \stackrel{\text{def}}{=} \Delta_{-1}' = \mathbf{1}$ and $H_U^{-1,(\ell')} \stackrel{\text{def}}{=} \Delta_{\ell-1}' = U_0' = H_U^0$. In general, for $-1 \leq j < \ell-1$ define

$$k_j \stackrel{\text{def}}{=} \ell' - \sum_{j \leq i < \ell-1} \epsilon_i.$$

Then $k_{-1} = 0$. With $k_{-1} = 0$, note that we have defined $H_U^{-1,(k_{-1}+n)}$ for $n = 0, \ldots, \ell'$.

Define $\Gamma_{-1}' = \mathbf{1}$. Note that $\Gamma_0' = \Delta_0'$.

II. For $j = 0, \ldots, \ell-2$:
DO

1. We are given H_U^j and Γ_j'. We have found H_U^j as the sequence of subgroups

$$H_U^{j-1} = H_U^{j-1,(k_{j-1})}, H_U^{j-1,(k_{j-1}+1)}, \ldots, H_U^{j-1,(k_{j-1}+n)}, \ldots, H_U^{j-1,(\ell')} = H_U^j.$$

2. We now find H_U^{j+1}. We can do this in increments, finding $H_U^{j,(k_j+n)}$ and isomorphism $\alpha_j^{(k_j+n)}$ for $k_j \leq k_j+n \leq \ell'$. We already know $H_U^{j,(k_j)} = H_U^j = H_U^{j-1,(\ell')}$. Define the isomorphism $\alpha_j^{(k_j)} = \eta_{j-1}' \circ \alpha_{j-1}^{(\ell')}$, where η_{j-1}' is the isomorphism

$$\eta_{j-1}' : H_U^{j-1}/\Gamma_{j-1}' \to H_U^{j-1*}/\Gamma_j'$$

given by (2) of Lemma 6 using $H_U^{j-1*} = H_U^{j-1}\Gamma_j'$ in the hypothesis. Then

$$\alpha_j^{(k_j)} : H_U^j/U_0' \to H_U^{j-1*}/\Gamma_j'.$$

(For $j = 0$, define $\alpha_0^{(k_0)}$ to be the trivial isomorphism $\alpha_0^{(k_0)} : \mathbf{1} \to \mathbf{1}$.)

We now consider some specific details of each increment n. First consider $k_j + n = k_j + \epsilon_j$. If $\epsilon_j = 0$, there is nothing to do except define $\Gamma'_{j+1} \overset{\text{def}}{=} \Gamma'_j$.

If $\epsilon_j = 1$, we find $H_U^{j,(k_j+\epsilon_j)}$ such that

(i) $H_U^{j,(k_j+\epsilon_j)} \supset H_U^{j,(k_j)}$.

(ii) $H_U^{j,(k_j+\epsilon_j)}$ is an extension of U'_0 such that there is an isomorphism $\alpha_j^{(k_j+\epsilon_j)}$,

$$\alpha_j^{(k_j+\epsilon_j)} : \frac{H_U^{j,(k_j+\epsilon_j)}}{U'_0} \to \frac{H_U^{j-1,(k_{j-1}+\epsilon_{j-1}+\epsilon_j)}}{\Gamma'_j},$$

whose restriction to $H_U^{j,(k_j)}/U'_0$ is $\alpha_j^{(k_j)}$.

(iii) $H_U^{j,(k_j+\epsilon_j)} = H_U^{j,(k_j)}(\Gamma'_{j+1})$, where subgroup $\Gamma'_{j+1} \subset H_U^{j,(k_j+\epsilon_j)}$ satisfies

$$\begin{aligned} \Gamma'_{j+1} \cap H_U^{j,(k_j)} &= \Gamma'_j, \\ \Gamma'_{j+1}/\Gamma'_j &\simeq \Delta'_{j+1}/\Delta'_j, \\ \Gamma'_{j+1} &\lhd H_U^{j,(k_j+\epsilon_j)}. \end{aligned}$$

We also require that

$$H_U^0, H_U^1, \ldots, H_U^j \lhd H_U^{j,(k_j+\epsilon_j)}.$$

For the remaining increments, for n satisfying $k_j+\epsilon_j < k_j + n \leq \ell'$, we just need to find $H_U^{j,(k_j+n)}$ such that

(i) $H_U^{j,(k_j+n)} \supset H_U^{j,(k_j+n-1)}$.

(ii) $H_U^{j,(k_j+n)}$ is an extension of U'_0 such that there is an isomorphism $\alpha_j^{(k_j+n)}$,

$$\alpha_j^{(k_j+n)} : \frac{H_U^{j,(k_j+n)}}{U'_0} \to \frac{H_U^{j-1,(k_{j-1}+\epsilon_{j-1}+n)}}{\Gamma'_j},$$

whose restriction to $H_U^{j,(k_j+n-1)}/U'_0$ is $\alpha_j^{(k_j+n-1)}$.

We also require that

$$H_U^0, H_U^1, \ldots, H_U^j \lhd H_U^{j,(k_j+n)}$$

and $\Gamma'_{j+1} \lhd H_U^{j,(k_j+n)}$.

ENDDO

III. For $j = \ell - 2$, part II is abbreviated since $k_{\ell-2} + \epsilon_{\ell-2} = k_{\ell-2} + 1 = \ell'$. Then $H_U^{\ell-2,(k_{\ell-2}+\epsilon_{\ell-2})}$ is the state group H_U of a shift group that is a subdirect product group. •

We can implement increment $k_j+n = k_j+\epsilon_j$ as follows. Since $H_U^{j,(k_j+\epsilon_j)} = H_U^{j,(k_j)}(\Gamma'_{j+1})$, from (4) of Lemma 6 we have

$$\frac{H_U^{j,(k_j+\epsilon_j)}}{\Gamma'_j} \simeq \frac{H_U^{j,(k_j)}}{\Gamma'_j} \times \frac{\Gamma'_{j+1}}{\Gamma'_j} \overset{\text{def}}{=} H^\times.$$

Thus we first find a group Γ'_{j+1}/Γ'_j isomorphic to Δ'_{j+1}/Δ'_j. Then form the direct product group $H^\times$. Now find $H_U^{j,(k_j+\epsilon_j)} \supset H_U^{j,(k_j)}$ an extension of Γ'_j by $H^\times$ such that $H_U^{j,(k_j+\epsilon_j)}$ contains a normal subgroup Γ'_{j+1} which is an extension of Γ'_j by Γ'_{j+1}/Γ'_j. Now check whether (ii) is satisfied. Note that the direct product group $H^\times$ gives some insight into the structure of the state group and explains why D_8 can be the state group of the V.32 code [6].

The algorithm can be improved by using a composition chain of H_U, as obtained for G in Theorem 15; this approach somewhat resembles the cyclic extension method [24].
